

Experimental particle physics at the LHC (1)

Kerstin Tackmann (DESY)

GRK1504/2: Autumn Block Course 2016

Particle physics and the Large Hadron Collider

The Standard Model very successfully describes (laboratory-based) measurements

- Sometimes to amazing accuracy: the limit on the electron dipole moment has been verified to $\mathcal{O}(10^{-27})$

...but we also have hints that it may not be the end of the story...

- What is the origin of the matter/antimatter asymmetry in the universe?
- What is dark matter?
- How do neutrinos acquire mass?

...and would like to understand more...

- Are the forces unified at high energies?
- What did the early universe look like?
- Do we (really) understand why elementary particles have mass?
- ...

The LHC is studying physics at high energies (and high luminosities), trying to answer (some of) these questions

Experimental particle physics at the LHC – menu

Topics of the lectures

- Overview LHC, proton collisions, and the experiments
- A close look at the $H \rightarrow \gamma\gamma$ analysis: analysis techniques
- Overview of Higgs measurements and searches in other decay channels and combined results
- Overview of non-Higgs results (if time allows)

General remarks

- Please interrupt to ask questions!
- In most cases I will use ATLAS examples

Many thanks to Peter Jenni, Andreas Hoecker, Sandra Kortner, Manuella Vinciter, Markus Elsing, Heather Gray, and Witold Kozanecki for material used in these slides.

Why a hadron collider?

Energy loss from synchrotron radiation in a circular collider (per turn)

$$\Delta E = \frac{q^2}{3R\epsilon_0} \left(\frac{E}{mc^2} \right)^4 \quad \frac{\Delta E_e}{\Delta E_p} = \left(\frac{m_p}{m_e} \right)^4 \sim 10^{13}$$

→ Higher energies much easier to reach with proton collisions

But protons also have disadvantages ...

- ...only part of the protons' energies is available for the partonic collision
- ...unknown boost along the beam direction (incomplete kinematic information)
- ...large probability for low-energy processes
- ...strong interaction makes theoretical predictions more complicated

Large Hadron Collider (@CERN, Geneva)

LHC uses LEP tunnel

- Circumference ~ 26.7 km
- ~ 100 m below the surface

Design: pp collisions at $\sqrt{s} = 14$ TeV

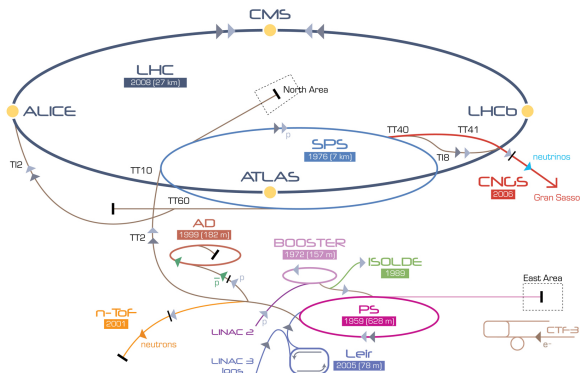

pp collisions at

- 2009 $\sqrt{s} = 900$ GeV
- 2010/11 $\sqrt{s} = 7$ TeV
- 2012 $\sqrt{s} = 8$ TeV
- 2015/16 $\sqrt{s} = 13$ TeV
- 2013/14 shutdown: machine and detector consolidation

in addition p -lead and lead-lead collisions

The LHC (pre-)accelerator chain

Linac 60 MeV

Booster 1.4 GeV

PS 25 GeV

SPS 450 GeV

LHC 3.5-7 TeV

>50 years of CERN history
still operational

Previous main accelerator
turns into pre-accelerator
for the next step

▶ p [proton] ▶ ion ▶ neutrons ▶ \bar{p} [antiproton] ▶ p/\bar{p} [proton/antiproton conversion] ▶ neutrinos ▶ electron

LHC magnets

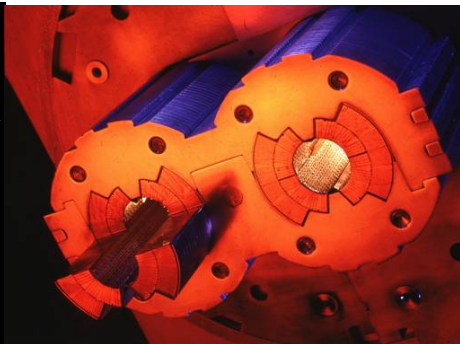

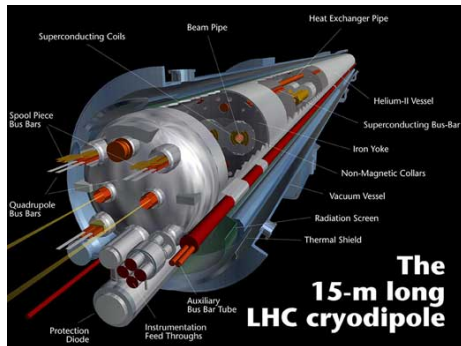

~ 6700 magnets controlling the beams

Dipoles	bending	1232
Quadrupoles	focusing	400
Sextupoles		2464
Octupoles/decapoles		1568
Orbit correctors		642
Others		376

Quadrupoles (inner triplet)

Technical challenge: dipole magnets

Keeping a proton with momentum p on circular orbit

$$p(\text{TeV}) = 0.3B(\text{T})R(\text{km})$$

For $p = 7 \text{ TeV}$ and $R = 4.3 \text{ km}$ need $B = 8.4 \text{ T} \rightarrow 12 \text{ kA}$

\rightarrow need superconducting magnets (normal conducting magnet would melt):
Nb-Ti cooled to 1.9 K with pressurized superfluid Helium

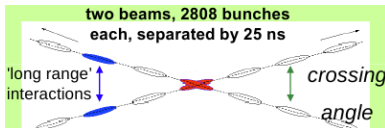

LHC design parameters

beam energy	7	TeV
instantaneous luminosity	10^{34}	$\text{cm}^{-2}\text{s}^{-1}$
integrated luminosity/year	~ 100	fb^{-1}
dipole field	8.4	T
dipole current	11700	A
circulating current/beam	0.53	A
number of bunches	2808	
bunch spacing	25	ns
protons per bunch	10^{11}	
rms beam radius at IP1/5	16	μm
rms bunch length	7.5	cm
stored beam energy	360	MJ
crossing angle	300	μrad
number of events per crossing	20	
luminosity lifetime	10	h

Beam energy stored in each LHC beam 360 MJ

Equivalent to

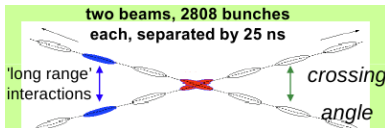

- Kinetic energy: 450 cars at 100 km/h
- Chemical energy: 70 kg of chocolate

...but this is not how LHC has been operating so far

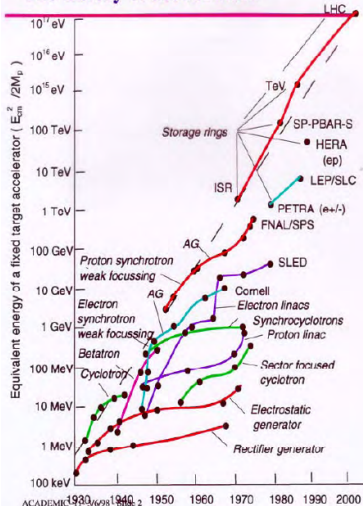

LHC design parameters

beam energy	7	TeV
instantaneous luminosity	10^{34}	$\text{cm}^{-2}\text{s}^{-1}$
integrated luminosity/year	~ 100	fb^{-1}
dipole field	8.4	T
dipole current	11700	A
circulating current/beam	0.53	A
number of bunches	2808	
bunch spacing	25	ns
protons per bunch	10^{11}	
rms beam radius at IP1/5	16	μm
rms bunch length	7.5	cm
stored beam energy	360	MJ

number of events per crossing	20	
luminosity lifetime	10	h

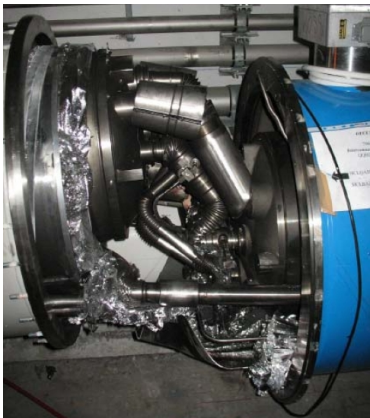

...but this is not how LHC has been operating so far

The history of accelerators

exponential development

LHC operations

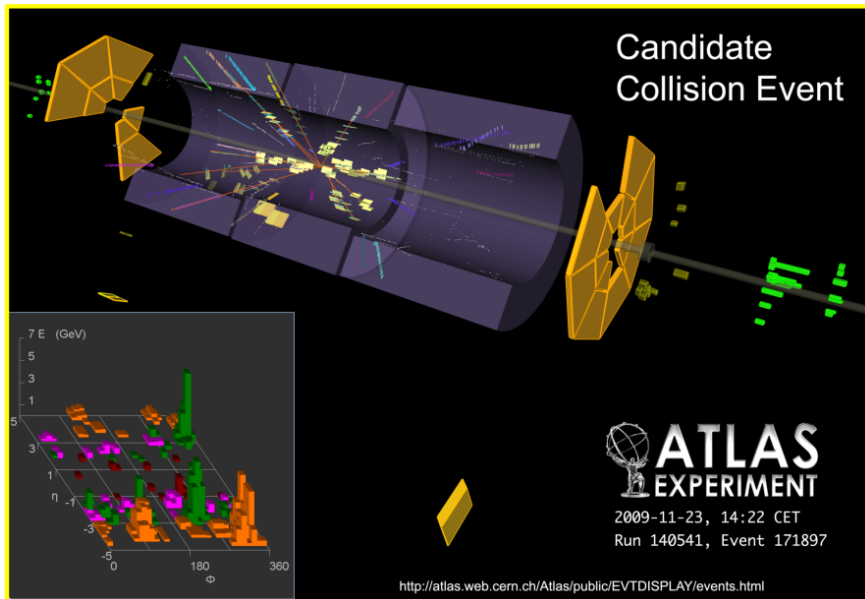

On September 19, 2008 one superconductor joint failed, damaged the vacuum enclosure, caused a catastrophic release of Helium and collateral damage (up to 50 cm displacement of several quadrupoles, beam pipe contaminated with soot, ...)

~ 1 year of repairs and improvements

Highest safe energy for operation was determined to be 3.5 TeV per beam (given measured resistance in joints)

- Operation with 1400 bunches, i.e. 50 ns bunch spacing

First collisions at 900 GeV (end of 2009)

Luminosity and event rate

Rate of events N produced for a process with cross section σ

$$dN/dt = \mathcal{L}\sigma$$

Luminosity depends on the beam parameters

$$\mathcal{L} = \frac{N_p^2 n_{\text{bunch}} f}{A}$$

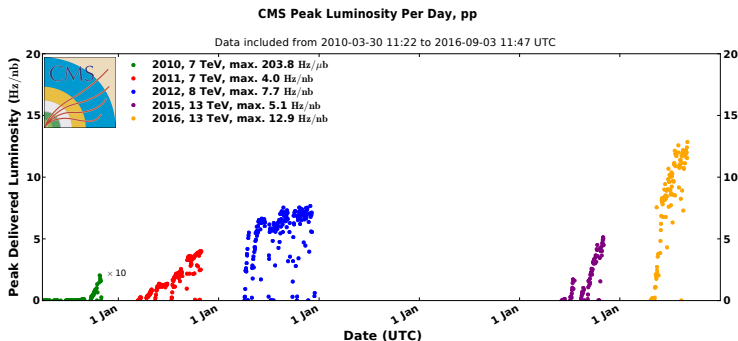

with

- N_p number of protons/bunch (10^{11})
- n_{bunch} number of bunches (2808)
- f revolving frequency (11245 Hz)
- A effective cross section area of beams

Integrated luminosity

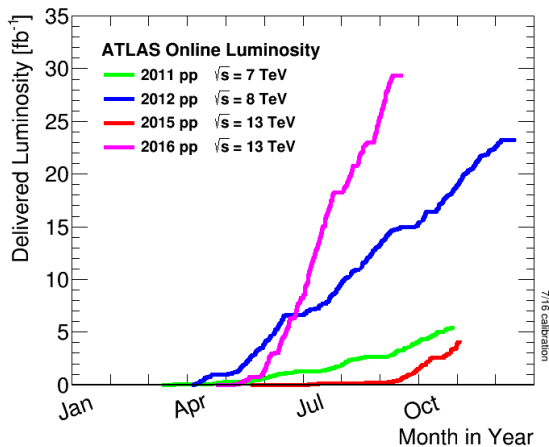

$$L = \int \mathcal{L} dt$$

Instantaneous luminosity at LHC

- Significant increase of instantaneous luminosity over time
 - ★ Increase of number of bunches, protons per bunch, more tightly focused beam
 - ★ Operation with 25 ns bunch spacing since summer 2015
- Design instantaneous of $1 \times 10^{34} \text{ cm}^{-2} \text{ s}^{-1}$ surpassed this summer

Integrated luminosity

2016 29.3 fb^{-1}

2012 23.3 fb^{-1}

2011 5.6 fb^{-1}

2015 4.2 fb^{-1}

2010 0.048 fb^{-1}

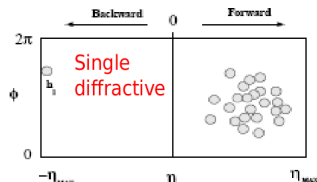

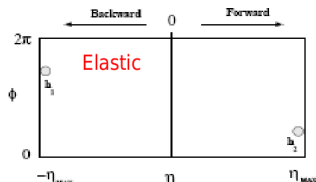

- In most years LHC has outperformed expectations
 - ★ E.g. at the beginning of 2011, we were hoping for $\sim 1 \text{ fb}^{-1}$
- Efficiency (delivered by LHC \rightarrow analyzed) $\sim 90\%$

Total pp cross section

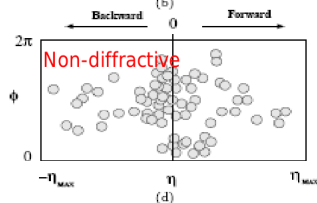

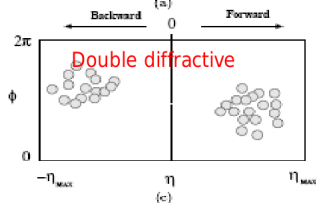

- Total pp cross section $\sigma_{\text{tot}} = \sigma_{\text{elastic}} + \sigma_{\text{inelastic}}$
- Inelastic term can be decomposed as

$$\sigma_{\text{inelastic}} = \sigma_{\text{single diffractive}} + \sigma_{\text{double diffractive}} + \sigma_{\text{non-diffractive}}$$

- Single (double) diffractive:
 $pp \rightarrow pX(XX)$,
clear gap

- Non-diffractive:
 $pp \rightarrow X$, gaps
filled by particles

Inelastic collisions per bunch crossing

- Number of inelastic collisions per bunch crossing

$$\langle \mu \rangle = \sigma_{\text{inel}} \mathcal{L} \Delta t / \epsilon_{\text{bunch}}^{\text{occupancy}}$$

- LHC $\langle \mu \rangle \approx 80 \text{ mb } 10^{34} \text{ cm}^{-2} \text{ s}^{-1} \cdot 25 \text{ ns} / 0.8 = 20 - 25$
 - ★ On average, >20 simultaneous pp collisions per bunch crossing

- Much more than at recent machines

- ★ LEP $\Delta t = 22 \text{ ms}$ and $\langle \mu \rangle \ll 1$
- ★ SppS $\Delta t = 3.3 \text{ ms}$ and $\langle \mu \rangle \approx 3$
- ★ HERA $\Delta t = 96 \text{ ns}$ and $\langle \mu \rangle \ll 1$
- ★ Tevatron $\Delta t = 0.4 \text{ ms}$ and $\langle \mu \rangle \approx 2$

The price of high luminosity: many events overlayed in the detector

ATLAS was designed to operate with 23 interactions overlayed

Measurement of the luminosity (I)

$$\mathcal{L} = \frac{\mu n_{\text{bunch}} f}{\sigma_{\text{inel}}} = \frac{\mu_{\text{eff}} n_{\text{bunch}} f}{\sigma_{\text{eff}}}$$

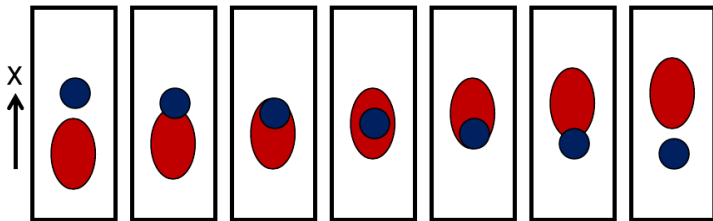

- μ inelastic interactions per bunch crossing
- μ_{eff} measured number of interactions per bunch crossing
- σ_{eff} effective cross section, needs to be calibrated

Luminosity monitoring algorithms

- Event counting: dedicated lumi monitor (LUCID), beam conditions monitor (BCM) (“How many bunch crossings see an event?”)
 - ★ Count fraction of bunch crossings without events
 - ★ \mathcal{L} is monotonic (non-linear) function of the event rate
- Track (+primary vertex) counting: tracking detectors
- Flux counting: currents in the calorimeters

Measurement of the luminosity (II)

- Measure **visible interaction rate** μ_{eff} as a function of beam separation δ in beam profile scans

Measurement of the luminosity (II)

- Measure **visible interaction rate** μ_{eff} as a function of beam separation δ in beam profile scans

- Measured reference luminosity

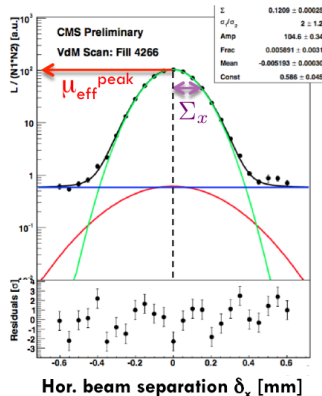

$$\mathcal{L} = \frac{N_p^2 n_{\text{bunch}} f}{2\pi \Sigma_x \Sigma_y}$$

with $\Sigma_{x,y}$ from the scan curve

- Allows direct calibration of the effective cross section σ_{eff} (for each luminosity detector/algorithm)

$$\sigma_{\text{eff}} = \underbrace{\mu_{\text{eff}}^{\text{peak}}}_{\text{peak rate}} \frac{2\pi \underbrace{\Sigma_x \Sigma_y}_{\text{scan widths}}}{\underbrace{n_1 n_2}_{\text{bunch populations}}}$$

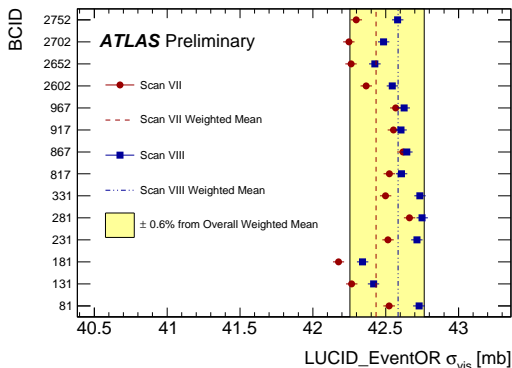

effective cross-section

- Assumption: can factorize into scan in x and y (not completely true)

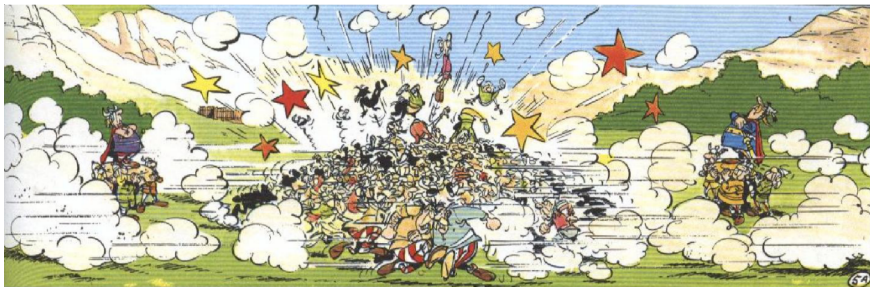

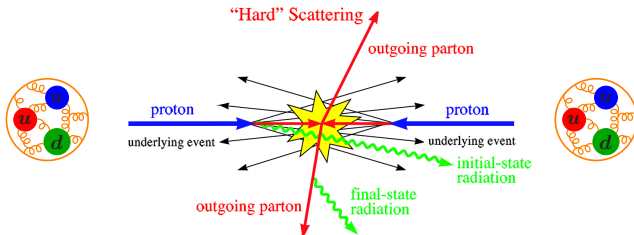

Measurement of the luminosity (II)

σ_{eff} measured in 2011 in LUCID (two different scans)

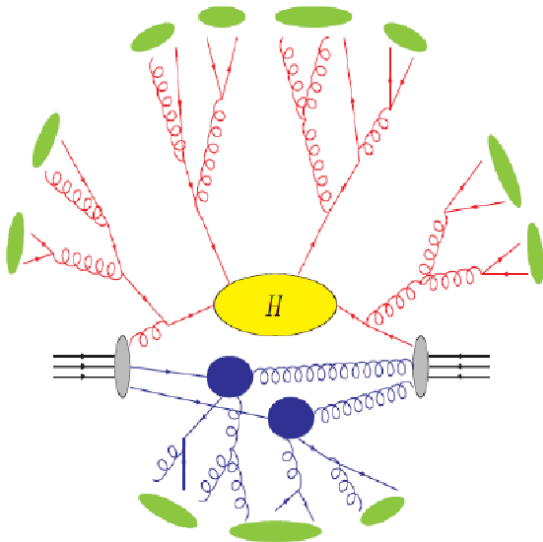

- Yellow band: uncertainty assigned from variations between scans and BCID
- Typical uncertainty on luminosity measurement 2-3%

Proton collisions are a bit messy...

Proton collisions in detail...

...or rather, how we simulate them...

+ Decay

Hadronization of partons to hadrons, nonperturbative model

Parton shower: splitting of partons → modeling initial and final state radiation

Hard scatter described by matrix element (perturbative)

Proton structure: partons inside the proton

Multiple parton interactions: interactions of remaining partons in protons

Cross sections

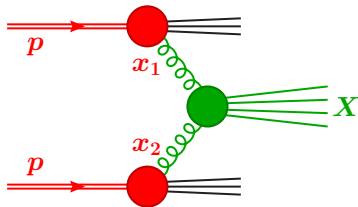

Cross section (σ) is the probability that a process $a + b \rightarrow X$ occurs when a and b collide

- Differential cross section $d\sigma/dy$ is the probability for final state with given y
 - ★ Example: jet transverse momentum spectrum $d\sigma/dp_T$

Proton collisions: For inclusive processes $\sigma(pp \rightarrow X)$ can be computed via factorization theorem, separating the **short distance** and **long distance**

$$\sigma_{pp \rightarrow X} = \sum_{a,b} \int_0^1 dx_1 dx_2 f_a(x_1, Q^2) f_b(x_2, Q^2) \hat{\sigma}_{ab \rightarrow X}(x_1, x_2, Q^2)$$

- ★ **Hard scattering:** production of W, Z , top, Higgs, ..., computed in perturbative QCD at scale Q^2
- ★ **Parton distribution functions** \rightarrow nonperturbative structure of the proton

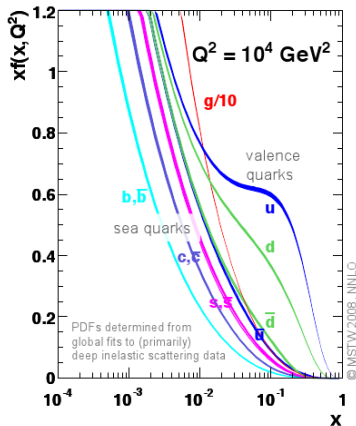

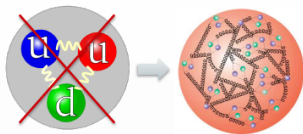

Note: strictly speaking only proven for inclusive processes

Parton distribution functions (pdfs)

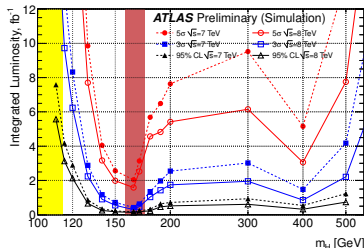

- Proton content: **valence quarks**, **sea quarks**, gluons
- Momentum distribution of partons described by pdfs, function of
 - ★ Momentum fraction (of proton momentum) x
 - ★ Q^2 (scale of hard process)
- CM energy for parton collision
 $\hat{s} = x_1 x_2 s (= m_X^2)$
- For $m_X = 100 \text{ GeV}$
 - ★ Tevatron ($\sqrt{s} = 2 \text{ TeV}$) $x = 0.22$ (if $x_1 = x_2$)
 - ★ LHC ($\sqrt{s} = 14 \text{ TeV}$) $x = 0.08$ (if $x_1 = x_2$)

- Larger cross sections at LHC
- LHC: cross section dominated by gg

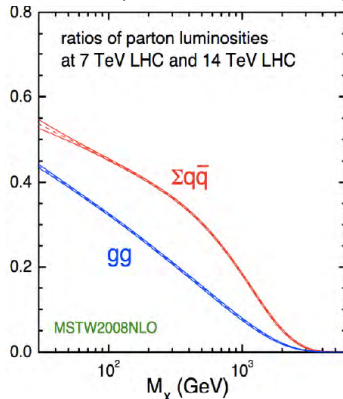

Aside: implication of running at lower \sqrt{s} in 2010-2012

- Lower $\sqrt{s} \rightarrow$ need larger x to have the same available energy
- \rightarrow Production of high-mass objects more difficult at lower \sqrt{s}
- \rightarrow More luminosity needed for discovery of new particles
 - ★ In particular for gg induced processes (like Higgs production)
 - ★ Relative behavior of signal and background processes also important

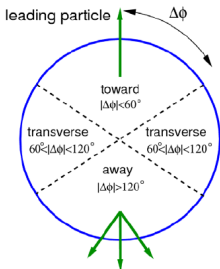

Ratio of parton luminosities at 7/14 TeV (from James Stirling)

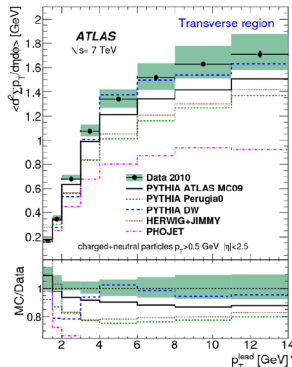

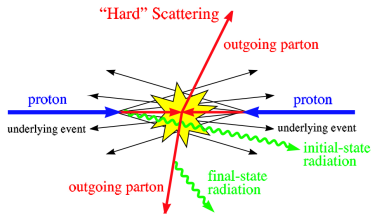

Underlying event

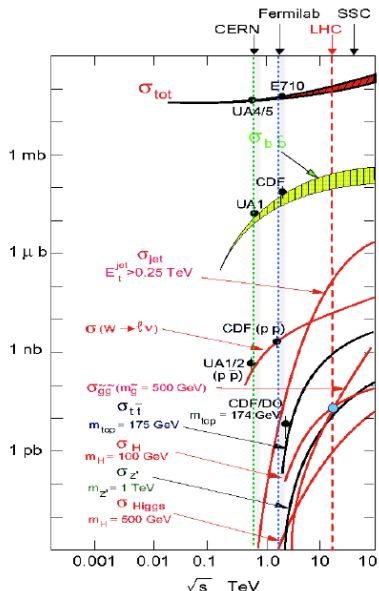

- Soft hadronic activity, produced in addition to the hard scattering
- Includes initial and final state radiation, multiple particle interactions and other soft effects
- Description in MC traditionally tuned using observables measured in the region transverse to the hard scatter axis

average Σp_T for stable particles per unit area in $\eta - \phi$ in transverse region as a function of p_T^{lead}

Production cross sections at hadron colliders

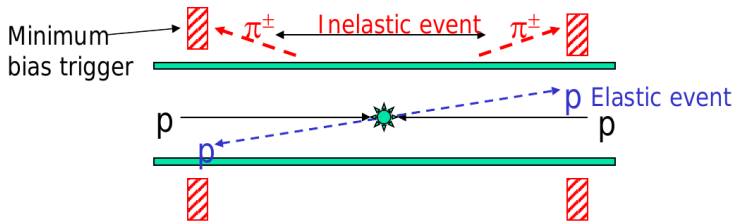

Process	Cross section (nb) at 14 TeV CM energy	Production rates (Hz) at $L=10^{34} \text{ cm}^{-2}\text{s}^{-2}$
Inelastic	10^8	10^9
$b\bar{b}$	5×10^5	5×10^6
$W \rightarrow \ell \nu$	15	150
$Z \rightarrow \ell\ell$	2	20
$t\bar{t}$	1	10
Z' (1 TeV)	0.05	0.5
$\tilde{g}\tilde{g}$ (1 TeV)	0.05	0.5
H (120 GeV)	0.04	0.4
H (180 GeV)	0.02	0.2

Many orders of magnitude between Higgs/New Physics and QCD backgrounds

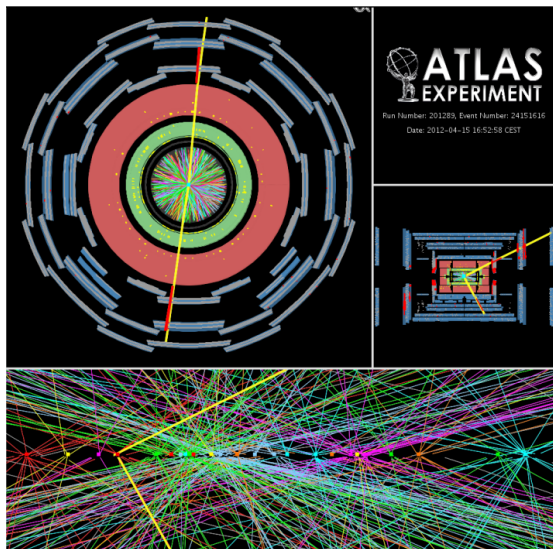

Minimum bias events

- “Any inelastic non-diffractive event” or “A generic pp inelastic non-diffractive event”
- Experimentally “anything that triggers the minimum bias trigger”
 - ★ This is effectively any non-single diffractive (nsd) inelastic event

- Minimum bias cross section fills almost the total inelastic cross section ($\sigma_{\text{inel}} = 80 - 85 \text{ mb}$, $\sigma_{\text{nsd}} = 65 - 70 \text{ mb}$)
- Mainly soft, nonperturbative, QCD interactions
- (Almost) all (additional) pp interactions in a recorded pp event are minimum bias events

Pileup

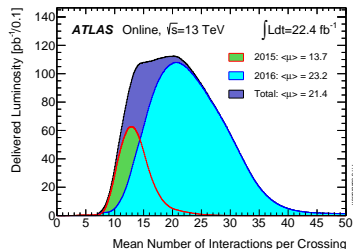

$Z \rightarrow \mu\mu$ with 25 interaction vertices

Challenge to trigger, software and analyses

- Large amount of data to process and store
- Identification and measurement of the “interesting” objects

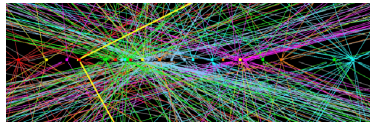

Especially for jets, E_T^{miss} and τ

In-time and out-of-time pileup

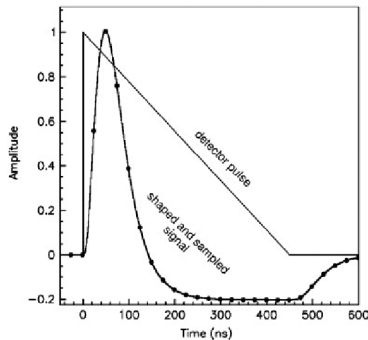

In-time

- Additional pp collisions occurring in the same bunch crossing as the collision of interest
- Can be suppressed by identifying pp collision vertex of interest

Out-of-time

- Additional pp collisions occurring in bunch crossings (just) before and after the collision of interest
- Typically corrected for on average
- E.g. ATLAS LAr calorimeter detector pulse ~ 450 ns
- Shaped by electronics such that average net contribution of in- and out-of-time pileup cancel for design running conditions

Kinematic variables

Transverse momentum p_T and missing transverse momentum “ E_T^{miss} ”

- Transverse momentum is conserved $\sum \vec{p}_T^i = 0$
- Large missing transverse momentum $E_T^{\text{miss}} = |\vec{p}_T^{\text{miss}}| \rightarrow$ invisible particle escaped detection (e.g. neutrino)

Longitudinal momentum p_z and (visible) energy E

- Boost of partonic CM unknown \rightarrow cannot use p_z and E conservation

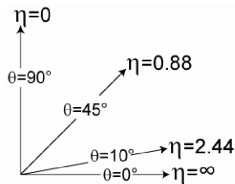

Polar angle θ

- Not Lorentz invariant

Pseudorapidity η and rapidity y

$$\eta = \frac{1}{2} \ln \frac{|\vec{p}| + p_z}{|\vec{p}| - p_z} = -\ln \left(\tan \frac{\theta}{2} \right) \quad (= y \text{ if } m = 0)$$

$$y = \frac{1}{2} \ln \frac{E + p_z}{E - p_z} = \frac{1}{2} \ln \frac{x_1}{x_2}$$

- Δy and p_T are invariant under longitudinal boosts
- Particle production in hadron colliders is roughly constant in y

The World of LHC...

ATLAS

- 2 T solenoid magnet
- Tracking: Si pixel, microstrip, straw tubes
- Transition radiation for e^\pm id
- Pb/LAr and steel/scint, Cu/LAr caloros
- μ chambers in ~ 0.4 T toroid field

24 m \times 45 m
7 ktons

ATLAS inner detector ($|\eta| < 2.5$)

Pixel detector

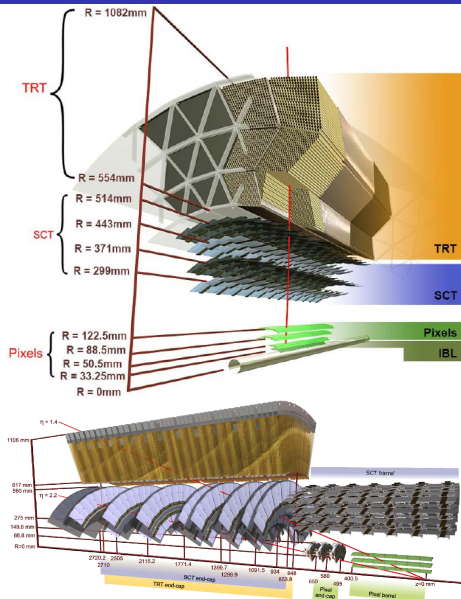

- 4 barrel layers, 2×3 endcap disks
- Innermost layer (IBL) installed for Run2 (33 mm radius)
- Pitch $50\ \mu\text{m} \times 400\ \mu\text{m}$ ($250\ \mu\text{m}$ for IBL)

Silicon microstrip detector (SCT)

- 4 barrel layers, 2×9 endcap disks
- Pitch $80\ \mu\text{m}$, 40 mrad stereo angle

Transition radiation tracker

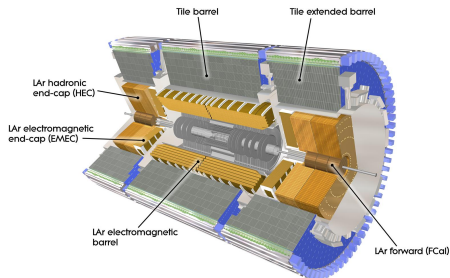

- Typically 36 straw-tube hits per track
- Transition radiation in scintillators to identify electrons

ATLAS calorimeters

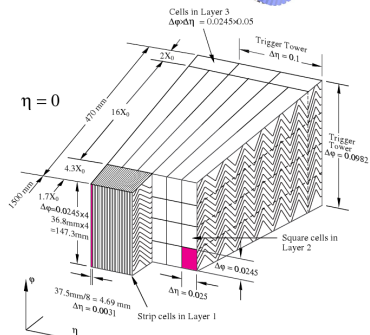

Electromagnetic calo ($|\eta| < 3.2$)

- Pb/LAr sampling calorimeter
- Radiation hard
- 3 longitudinal layers with accordion geometry and presampler inside of cryostat
- Fine lateral segmentation \rightarrow measure shower shape

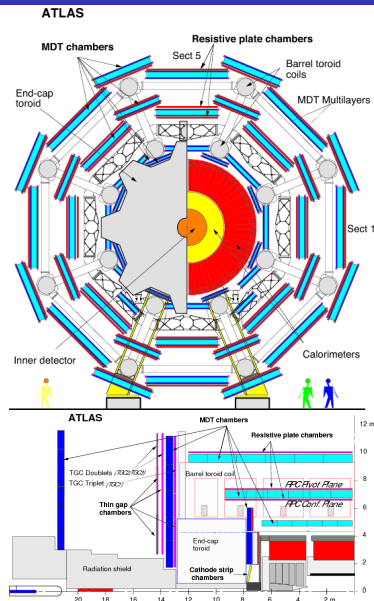

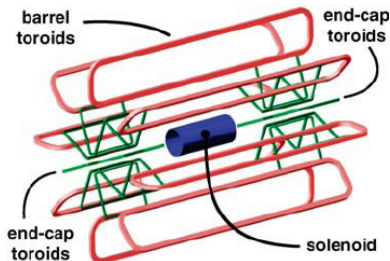

Hadronic calo

- Iron/plastic scintillator tiles sampling calorimeter ($|\eta| < 1.7$)
- Copper (EC) and tungsten (FCal)/LAr sampling calorimeter ($|\eta| < 4.9$)

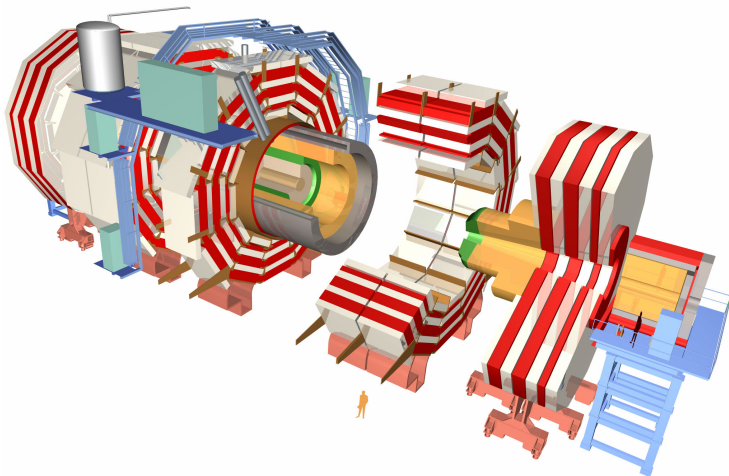

ATLAS muon spectrometer ($|\eta| < 2.7$)

- 3 barrel layers, 2×3 endcap wheels
- Fast trigger chambers: TGC (thin gap chambers), RPC (resistive plate chambers)
- High resolution tracking: MDT (monitored drift tubes), CSC (cathode strip chambers)
- Air-core toroids ($\langle B \rangle = 0.4 \text{ T}$)
 - ★ Large field variations in toroid, close to 4 T near coil

- 4 T solenoid magnet
- Tracking: Si pixel, microstrip

- PbWO_4 crystals and Fe/scint calos
- μ chambers in return yoke

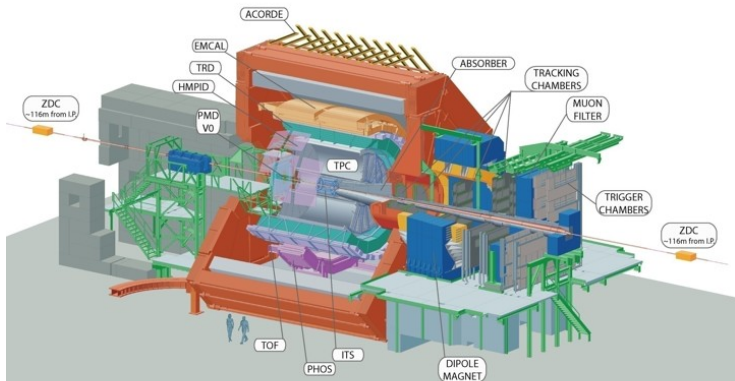

15 m × 22 m
12.5 ktons

Alice

Dedicated to heavy ion collisions (quark-gluon plasma), but also taking data during pp collisions

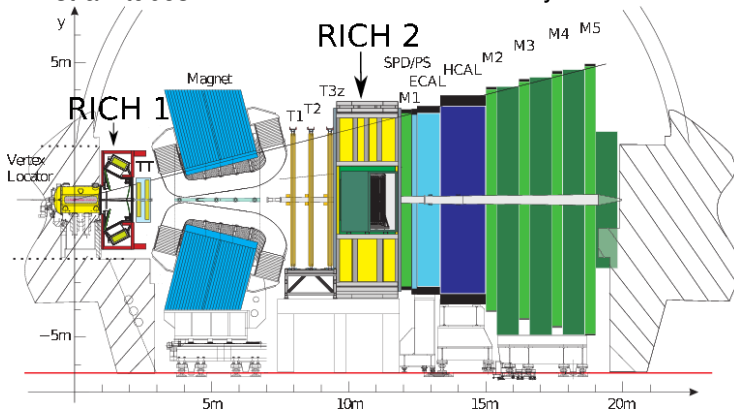

- L3 solenoid
- Tracking: Large TPC, Si pixel, drift and microstrip detectors
- PbWO_4 crystal and Pb/scint calo
- Particle id: RICH, TRD and TOF

16 m×26 m
10 ktons

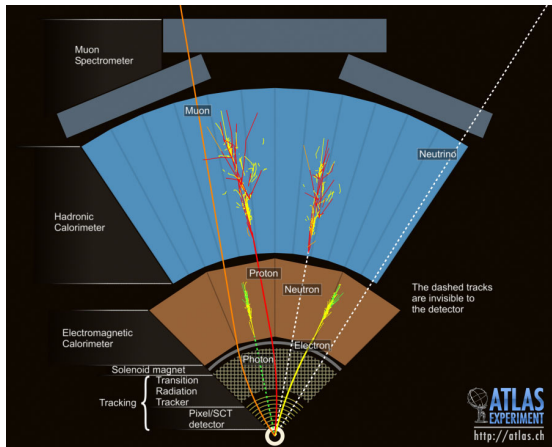

b physics and CP violation (indirect search for new physics)

- forward spectrometer
- dipole magnet
- Tracking: 21-layer Si microstrip, straw tubes
- Pb/scint and Fe/scint calorimeters
- Particle id: 2 RICH systems
- multiwire proportional chamber μ system

10 m × 13 m
× 21 m
5.6 ktons

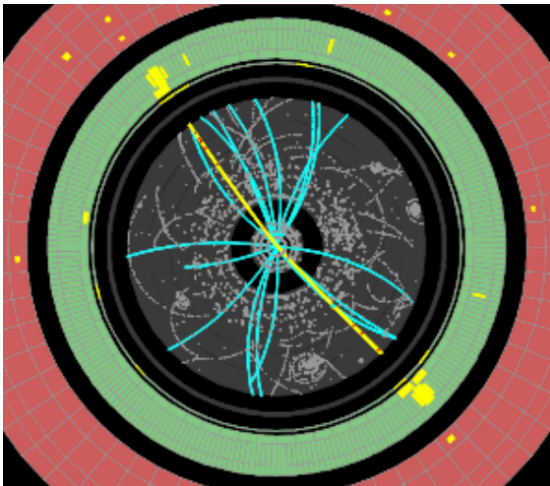

Object reconstruction (at ATLAS and CMS)

Electron

- Track in tracking system
- Shower in electromagnetic calorimeter
- No (or little) energy in hadronic calorimeter

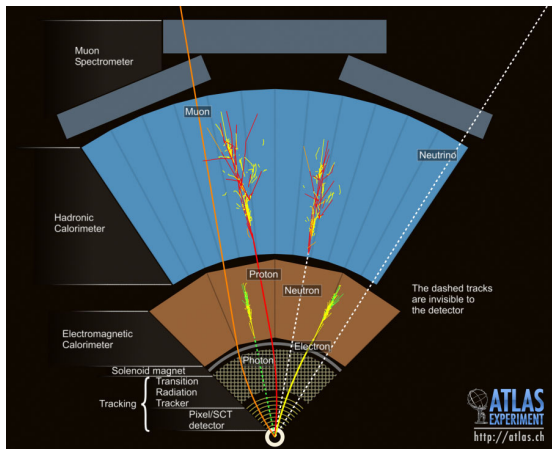

Object reconstruction (at ATLAS and CMS)

Electron

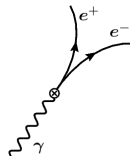

- Track in tracking system
- Shower in electromagnetic calorimeter
- No (or little) energy in hadronic calorimeter

Object reconstruction (at ATLAS and CMS)

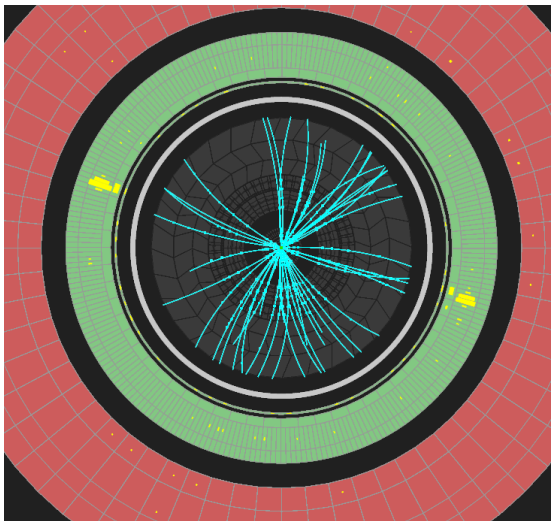

Photon

- No track or conversion vertex in tracking system
 - ★ $\sim 40\%$ of photons convert into e^+e^- due to high material budget
- Shower in electromagnetic calorimeter
- No (or little) energy in hadronic calorimeter

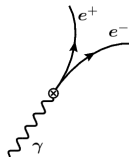

Object reconstruction (at ATLAS and CMS)

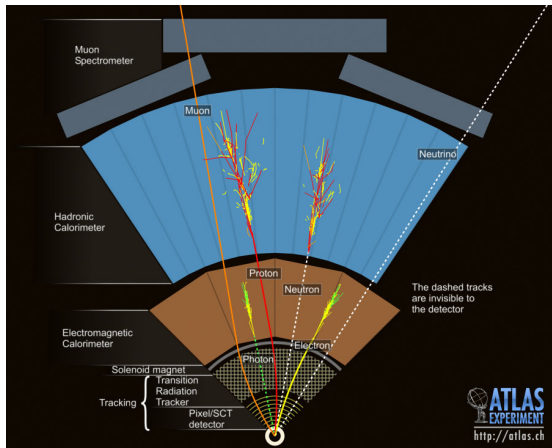

Photon

- No track or conversion vertex in tracking system
 - ★ $\sim 40\%$ of photons convert into e^+e^- due to high material budget
- Shower in electromagnetic calorimeter
- No (or little) energy in hadronic calorimeter

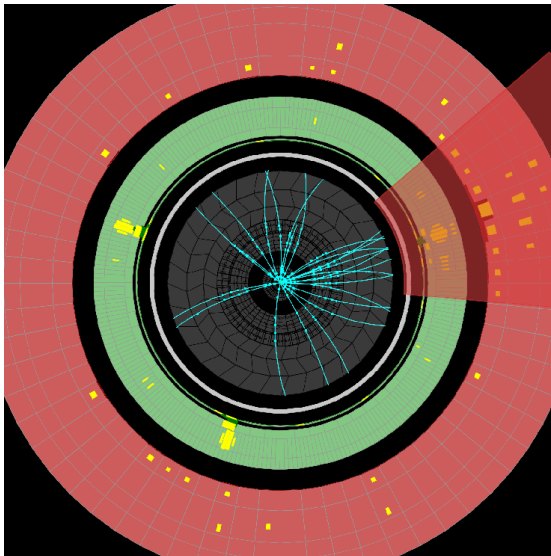

Object reconstruction (at ATLAS and CMS)

Hadron (Jet = hadronic shower)

- Tracks in tracking system (from charged component)
- Shower in hadronic and electromagnetic calorimeter

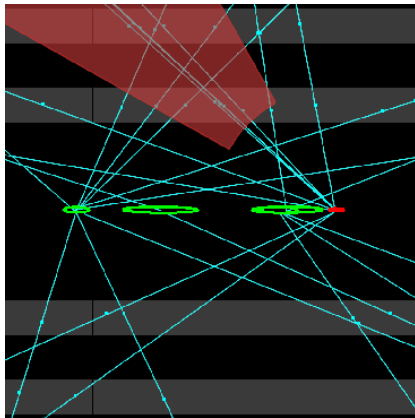

Object reconstruction (at ATLAS and CMS)

Hadron (Jet = hadronic shower)

Hadron (Jet = hadronic shower)

- Tracks in tracking system (from charged component)
- Shower in hadronic and electromagnetic calorimeter

b-jet

- Origin of tracks offset with respect to pp interaction vertex

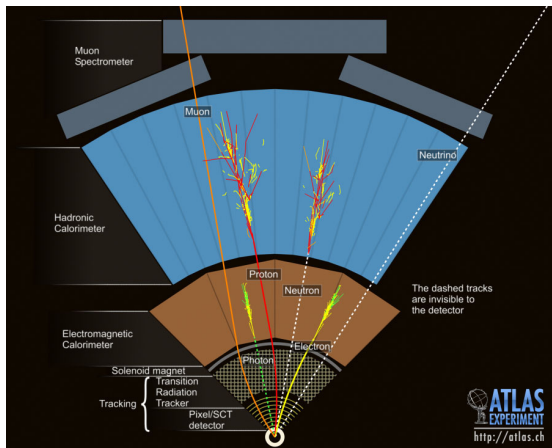

Object reconstruction (at ATLAS and CMS)

τ

- Hadronic (τ -jet):
Collimated, 1 or 3 tracks in tracking system
- Leptonic ($\tau \rightarrow e(\mu)\nu\nu$):
1 track: electron or muon

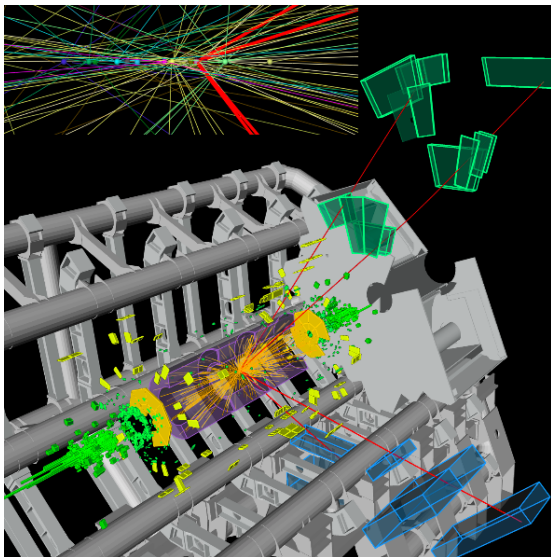

Object reconstruction (at ATLAS and CMS)

Muon

- Track in tracking system
- Little energy deposited in electromagnetic calorimeter
- Track in muon system

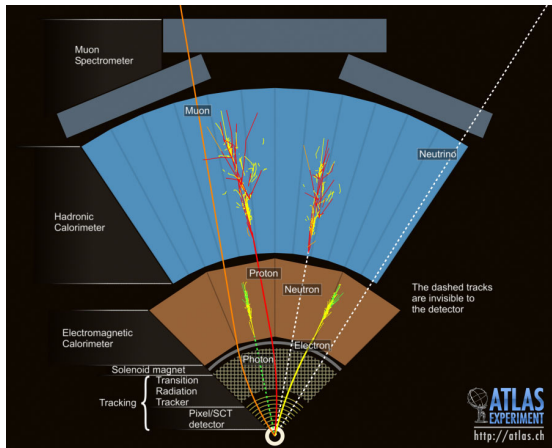

Object reconstruction (at ATLAS and CMS)

Muon

- Track in tracking system
- Little energy deposited in electromagnetic calorimeter
- Track in muon system

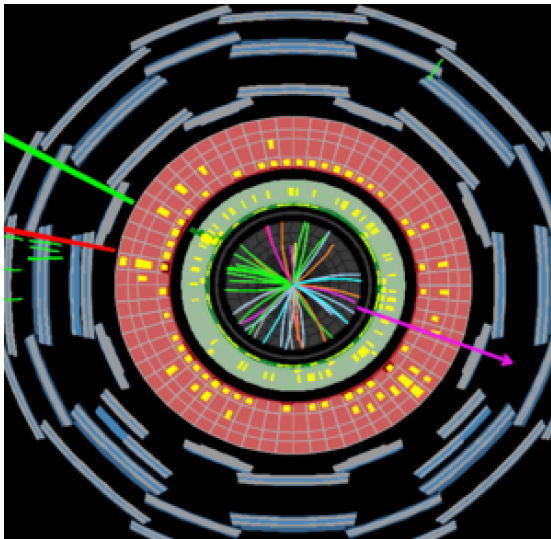

Object reconstruction (at ATLAS and CMS)

Neutrino (E_T^{miss})

- No signal in any subdetector
- Transverse energy imbalance in the event

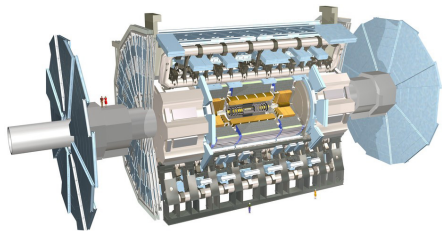

Object reconstruction (at ATLAS and CMS)

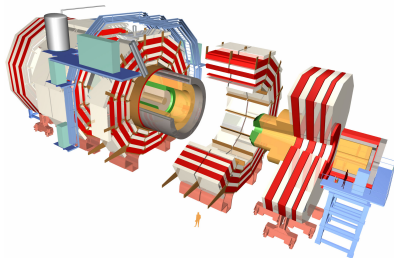

Neutrino (E_T^{miss})

- No signal in any subdetector
- Transverse energy imbalance in the event

The ATLAS and CMS experiments – comparison

ATLAS Emphasis on jet and missing E_T resolution, particle identification and standalone muon measurement

CMS Emphasis on electron/photon and tracking (muon) resolution

Both: excellent hermeticity and forward acceptance
