SP8: Photoelectron beam asymmetry studies at PITZ

Thursday 20 July 2017 10:21 (3 minutes)

The main task of PITZ facility (Photo Injector Test Facility at DESY, Zeuthen site) is developing and testing of photoelectron sources (photoelectron guns) for free-electron lasers like FLASH and European XFEL. The operation of the multiple gun prototypes discovered the presence of photoelectron beam asymmetries in transverse shape and projected emittance between x and y planes. The studies of the source of transverse beam asymmetry and its compensation by a pair of normal and skew quadrupoles are presented in this poster.
