The Colliding-Wind Binary Eta Carinae as seen with the H.E.S.S. telescopes

Eva Leser
for the H.E.S.S. Collaboration

TeVPA 2018 . Berlin

Eta Carinae

- Binary stellar system
- Properties:
 - Distance 2.3 kpc
 - Period of 5.54 yr
 - Last periastron May 2014
 - Eccentricity $e \sim 0.9$
 - Semi-major axis 16.64 AU (1.66 AU at periastron)
- Particle acceleration in shock regions
- Non-thermal emission predicted:
 - Radio and X-rays: Synchrotron radiation
 - Gamma-rays: from electrons via inverse Compton scattering, from protons via π^0 decay

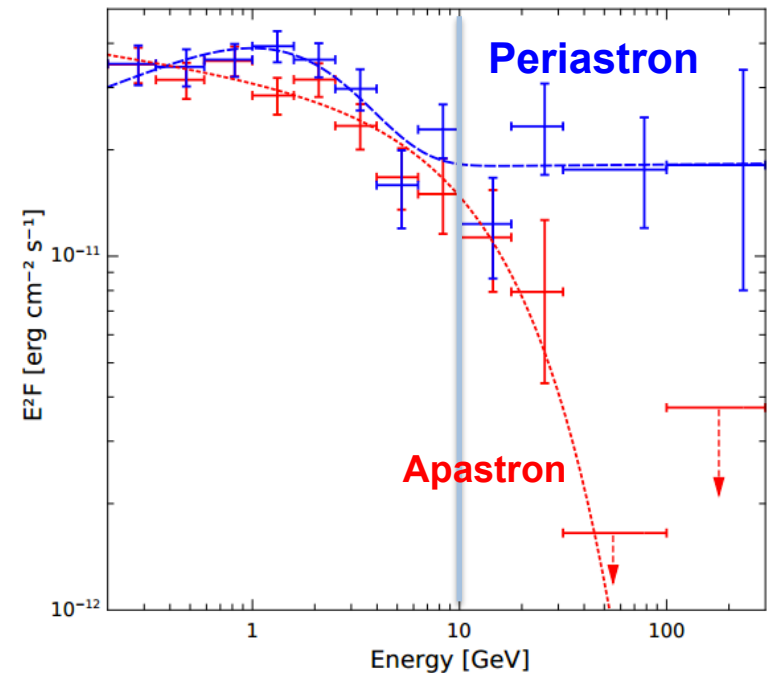

Primary: LBV type	Companion: O- or B-type
$M \sim 120 M_{\odot}$	$M \sim 30 M_{\odot}$
$\dot{M} \sim 5 \times 10^{-4} M_{\odot}/\text{yr}$	$\dot{M} \sim 10^{-5} M_{\odot}/\text{yr}$
$v_{w,\infty} \sim 500 \text{ km/s}$	$v_{w,\infty} \sim 3000 \text{ km/s}$

Eta Carinae in gamma-rays

- First detection by **AGILE** (Tavani et al. 2009)
- **Fermi-LAT**:
 - low- energy (0.2 – 10 GeV) & high-energy (10 – 300 GeV) components
 - Spectral variability in both components
- Search for VHE gamma-ray emission close to periastron

Spectral energy distribution (Fermi-LAT) covering 500 days of observations

Reitberger et al. (2015)

The High Energy Stereoscopic System: H.E.S.S.

- IACT in Southern hemisphere (Khomas Highland, Namibia)
- 4 telescopes with 12 m diameter (CT1-4), one 28 m diameter telescope (CT5)
- Energy range: 10s of GeV - 10s of TeV
- Camera Field of view: CT5 3.5°/ CT1-4 5° diameter
- Allows for single or multiple telescope observation modes

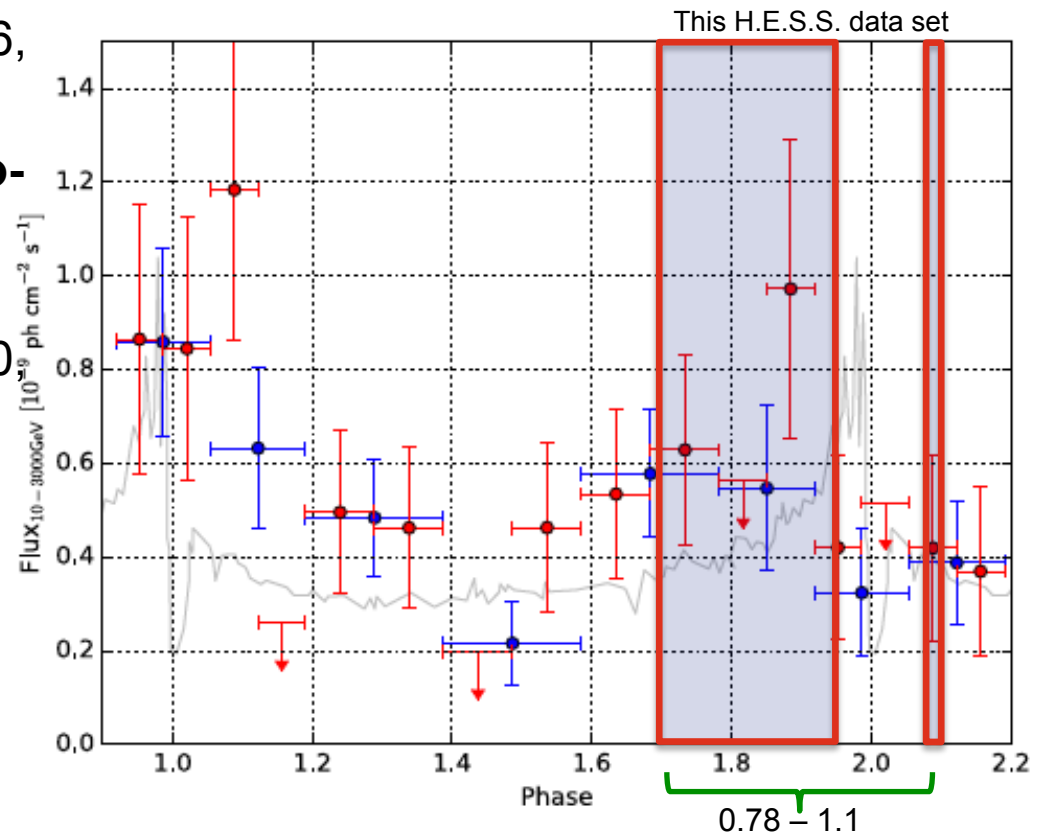

Photo: Mathieu De Naurois

The H.E.S.S. data set of 2014/2015

- (1 orbit = 5.54 yr)
- Coverage around periastron
- In total: 25.4 h
 - 12.1 h at phases 0.78 – 0.96, 68 % at phase 0.93
 - all five telescopes: **mono- and stereoscopic reconstruction**
 - 13.3 h at phases 0.96 – 1.10, 54 % at phase 1.09
 - 28 m diameter telescope only: only **monoscopic reconstruction** possible

=> Monoscopic reconstruction

Phase-binned flux 30 – 300 GeV by Fermi-LAT

Balbo & Walter (2017)

Night sky background in Eta Carinae ... in a H.E.S.S. camera

**Strong
inhomogeneities**

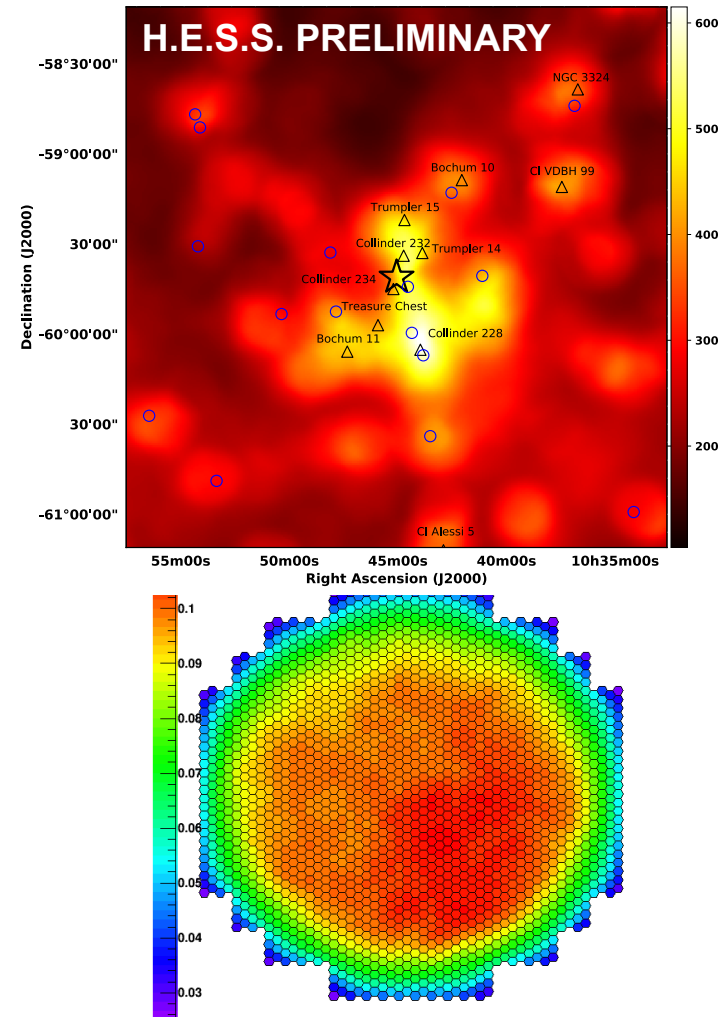

**x10 higher than in the
average H.E.S.S. FoV**

ESO/IDA/Danish 1.5m/R. Gendler, J.-E. Ovaldsen, C. Thöne, C. Feron

Handling the night sky background

- Hardware: increase pixel trigger threshold of Cherenkov camera
- Low-level data analysis: Increasing the shower image cleaning level
- Remaining noise is treated via:
 - Run-wise MC simulations for observations (correct NSB, turned-off pixels etc.)
 - Checks with different analysis methods and in-field high-NSB regions

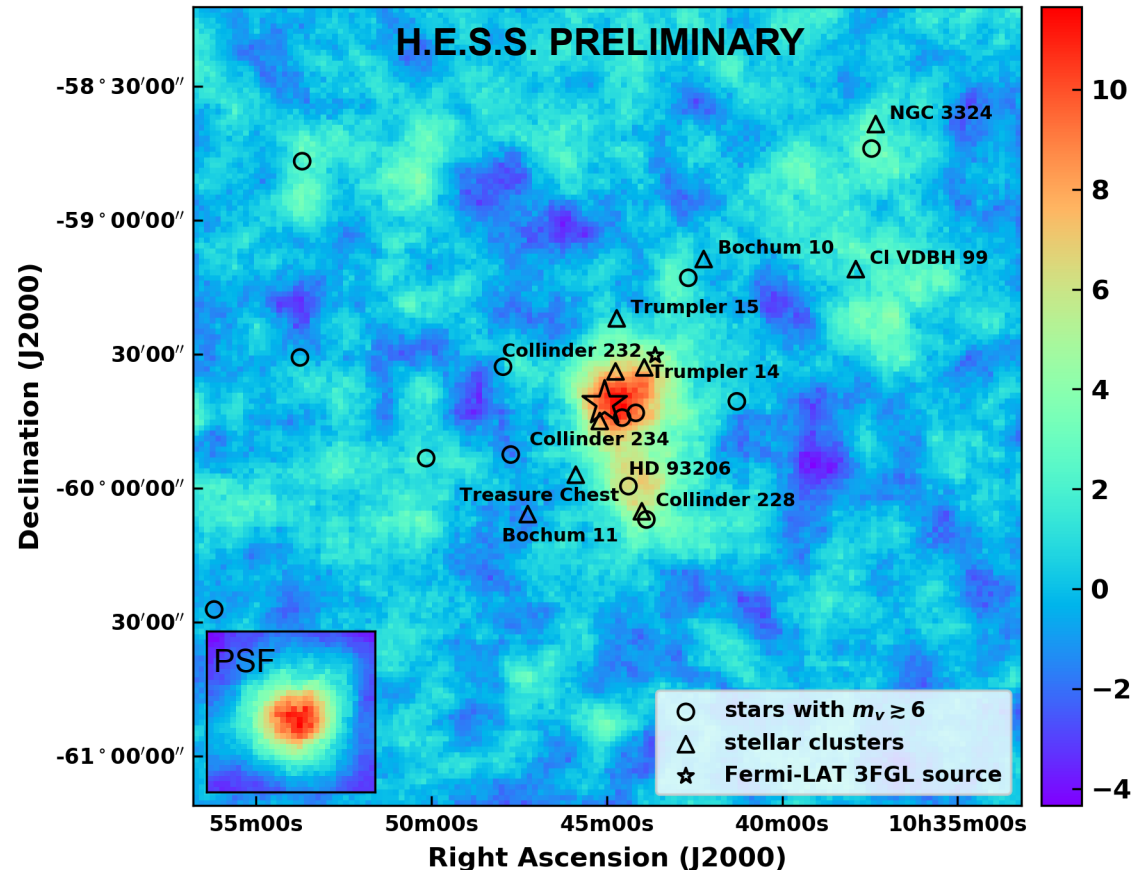

Night sky background in H.E.S.S. FoV in MHz

=> Extensive tests demonstrate that NSB is under control

Detection of Eta Carinae with H.E.S.S.

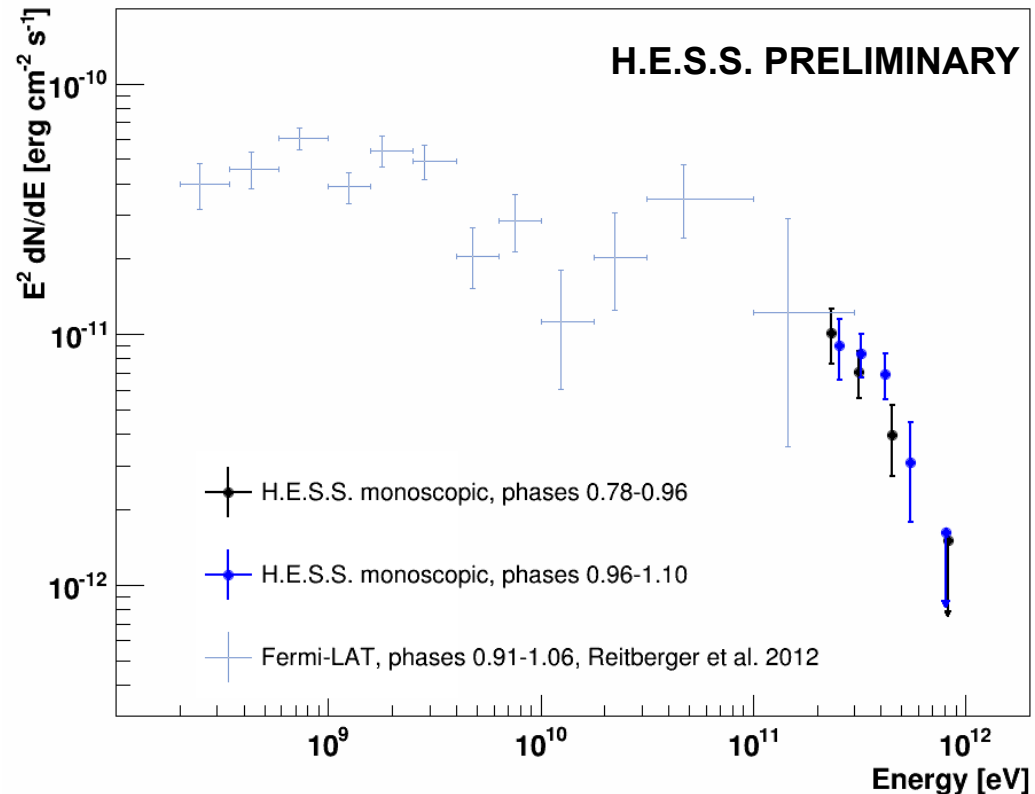

- CT5-mono data
Orbital phases:
 - 0.78 – 0.96
 - 0.96 – 1.10
- **Combined: 13.6 σ**
- 1070 γ in 25.4 h
- Energy threshold:
190 GeV
- VHE gamma-ray emission consistent with being point-like

Spectral Energy Distribution

Phases	0.78 - 0.96	0.96 - 1.10
Power-law index Γ	$3.94 \pm 0.35_{stat} \pm 0.96_{syst}$	$3.49 \pm 0.23_{stat} \pm 0.36_{syst}$
Threshold energy E_{th} [TeV]	0.19	0.22
Photon flux ($E > E_{th}$) [$\text{cm}^{-2} \text{s}^{-1}$]	$(1.76 \pm 0.19) 10^{-11}$	$(1.56 \pm 0.13) 10^{-11}$

- H.E.S.S. spectra before and after periastron agree within statistic uncertainties

Lightcurve from X-rays to VHE gamma rays

- Origin of emission inside wind-collision region -> variability along orbit expected
- No indication for variability in H.E.S.S. data with currently available statistics

H.E.S.S.

Fermi-LAT 10 – 300 GeV,
Balbo & Walter (2017)
Swift 2 – 10 keV,
Corcoran et al (2015)

Proposed scenarios for gamma-ray emission from Eta Carinae

■ Likely origin of gamma-ray emission

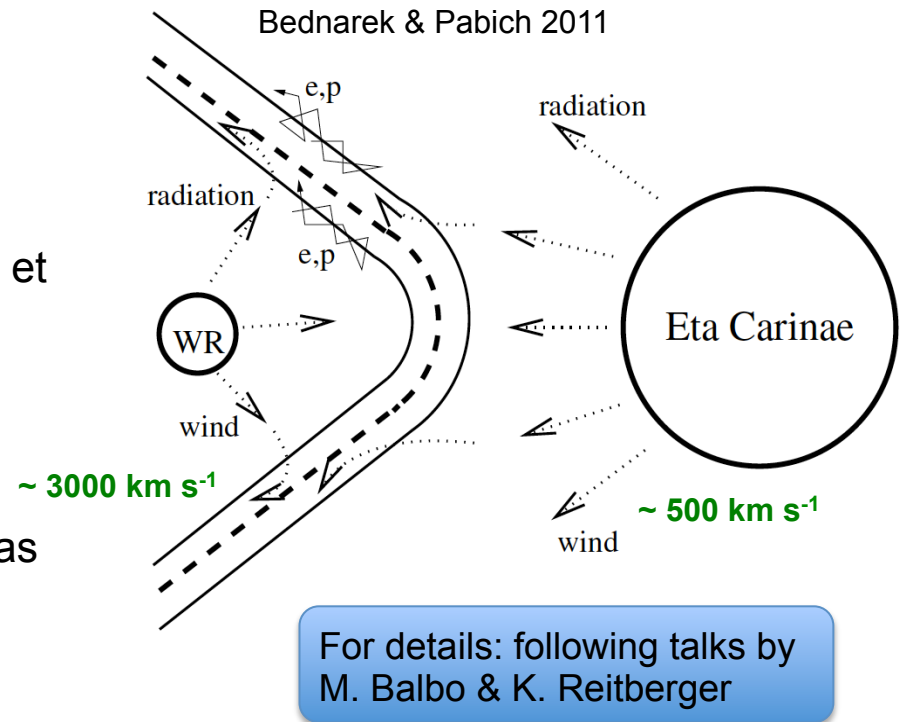

- In the colliding wind region
- Two shocks on both sides of the contact discontinuity (e.g. Bednarek et al. 2011)

■ Leptonic scenarios:

- Inverse Compton emission, two Fermi-LAT components interpreted as gamma/gamma absorption feature (Reitberger et al. 2012)

■ Mixed scenarios

- Low-energy component interpreted in leptonic (Farnier et al. 2011, Reitberger et al. 2015, Balbo & Walter 2017) and hadronic scenarios (Ohm et al. 2015)
- High-energy component often interpreted as hadronic in origin (Farnier et al. 2011, Reitberger et al. 2015, Ohm et al. 2015, Balbo & Walter 2017)

Ingredients for particle acceleration

- Last 2 σ spectral point in H.E.S.S. starts at 700 GeV
- Implications for parent particles?

- Electrons
 - Minimum required $E_e \sim \mathbf{700\ GeV}$ (Klein Nishina)
 - Balance between acceleration and synchrotron losses
 - $B < 0.2\ \text{G}$ required, $t_{\text{acc},e} \sim 5.4\ \text{h}$

- Protons
 - Minimum required $E_p \sim \mathbf{7\ TeV}$
 - In $B = 0.2\ \text{G}$ field, $t_{\text{acc},p} \sim 2\ \frac{1}{4}\ \text{days}$

- Gamma-ray luminosity $> 190\ \text{GeV}$ implies:
 - 6% of primary kinetic wind power in CWR into interacting CRs
 - 1% of companion kinetic wind power in CWR into interacting CRs

Summary and outlook

- VHE gamma-ray source coincident with Eta Carinae
- Careful investigation of NSB from the beginning, including detailed tailored simulations
- Maximum energy in gamma-rays 700 GeV
- Requires e^- with $E_e > 700$ GeV or p with $E_{pp} > 7$ TeV

- Further H.E.S.S. data available: Eta Carinae frequently observed since 2014
- Next periastron passage in December 2020 – full orbit of H.E.S.S. observations 🎉
- Paper in preparation

Backup – Discussion

- Last 2σ spectral point in H.E.S.S. starts at 700 GeV
- Implications for parent particles?
- For acceleration, assume
 - Diffusive shock acceleration (DSA) in strong shock (Bohm)
 - Shock velocity = companion wind velocity
 - Strong magnetic field

$$\tau_{\text{acc}} = 5 \times 10^4 \text{ s } v_{\text{sh},10^3 \text{ km s}^{-1}}^{-2} \frac{E_{\text{TeV}}}{B_G}$$

- Electron acceleration limited by synchrotron losses at $>\sim 100$ GeV
- For **electrons**: minimum required $E_e \sim 700 \text{ GeV}$ (Klein Nishina)

➔ $B < 0.2 \text{ G}$ required (in synchrotron cooling limit)

➔ acceleration time to reach required E_e : $t_{\text{acc},e} \sim 5.4 \text{ hr}$
