Drell-Yan production of heavy vectors in Higgs-less models

Jernej F. Kamenik

Institut "Jožef Stefan"

Introduction

- Experiments provide unambiguous indications that the SM gauge group is spontaneously broken $[SU(2)_L \times U(1)_Y \rightarrow U(1)_Q]$
- One elementary SU(2)_L scalar doublet with φ⁴ potential is the most economical & simple choice
- ⊗ L_{Higgs}(φ, Aⁱ,ψⁱ) = D_μφ⁺D_μφ + $µ^2$ φ⁺φ − λ (φ⁺φ) 2 + Y^{ij} Ψ_Lⁱ Ψ_R^j

c.f. talk by Pomarol

- o not the only allowed possibility
- So far only the ground state of this Lagrangian has been tested with good accuracy
 - ϕ < ϕ >=246GeV <-> m_W , m_Z
- Peskin & Takeuchi © [PRL65:964,1990]
 Altarelli & Barbieri [PLB253:161,1991]
- Some dynamical sensitivity to the Higgs mechanism is obtained from EWPO
 - Indirect indication of a light m_H (in the SM)

Do we need a fundamental Higgs field?

- EWPO indicate:
 - \circ a spontaneous breaking of SU(2)_L \times U(1)_Y
 - the breaking mechanism must respect, to a good accuracy, the custodial symmetry [$m_Z^2/m_W^2 \approx 1 + (g'/g)^2$]
- General formulation of the symmetry breaking mechanism in absence of a fundamental Higgs (or for large Higgs masses) in terms of a Chiral Lagrangian: $v^2 = v^2 + \nabla v + \nabla v$

 $\mathcal{L}_{\chi}^{(2)} = \frac{v^2}{4} \text{Tr}(D_{\mu} U^{\dagger} D^{\mu} U)$

U -> g_R U $g_L^+ = e^{i\pi/v}$ 3 Goldstones of the SM

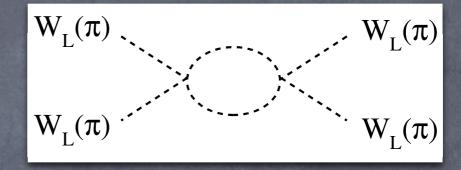

- Global: $SU(2)_L \times SU(2)_R \times U(1)_{B-L} -> SU(2)_{L+R} \times U(1)_{B-L}$
- \odot Local: $SU(2)_L \times U(1)_Y \longrightarrow U(1)_Q$

 $D_{\mu}U = -ig'B_{\mu}U + ig U W_{\mu}$

EW Chiral Lagrangian

$$\mathcal{L}_{eff} = \mathcal{L}_{gauge}(A^i, \psi^i) + \mathcal{L}_{Yukawa}(U, \psi^i) + \frac{v^2}{4} \text{Tr}(D_{\mu} U^{\dagger} D^{\mu} U)$$

- contains all the degrees of freedom we have directly probed in experiments
- naive cut-off dictated by the convergence of EW loops: Λ_{NDA} = 4πν ≈ 3 TeV
- perfectly describes particle physics up 3 TeV, beyond the tree level, with only two drawbacks
 - (point toward the existence of new degrees of freedom below the naive cut-off):
 - Violation of unitarity in W_LW_L → W_LW_L scattering (tree-level amplitude violates unitarity for s ≈ 1 TeV)
 - Bad fit to S and T

Introducing heavy vectors

- A natural alternative to Higgs-type mechanisms in curing the problem of unitarity in WW → WW scattering is represented by heavy vector fields
- Expected in many non-SUSY scenarios:
 - techni-rho in technicolor,
 - massive gauge bosons in 5-dimensional theories, hidden gaugemodels
- Difficult task is to cure at the same time unitarity and EWPO
 - can be analysed in general terms constructing an appropriate effective chiral Lagrangian with the heavy vectors as new explicit d.o.f.

$$\mathcal{L}_{\chi} = \frac{v^2}{4} \text{Tr}(D_{\mu} U^{\dagger} D^{\mu} U) + \mathcal{L}_{kin}(R, U, A_i; m_R) + \mathcal{L}_{int}(R, U, A_i; G_R)$$

Barbieri et al. [0806.1624]

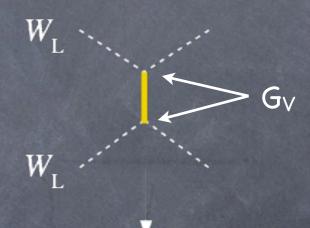

- Consider an effective theory based on the following two main assumptions:
 - The (new) dynamics that breaks the SM EW symmetry is invariant under the global symmetry $SU(2)_L \times SU(2)_R$ and under the discrete parity P: $SU(2)_L \leftrightarrow SU(2)_R$
 - One vector (V), or one vector + one axial-vector (V+A), both belonging to the adjoint representation of SU(2) L+R (triplets), are the only light fields below a cut-off Λ = 2-3 TeV
- Effective Lagrangian analysis based on ordering of operators according to the standard derivative (momentum) expansion

Unitarizing W_LW_L scattering

Barbieri et al. [0806.1624]

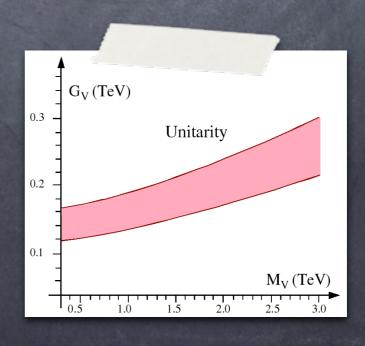

No tree-level violation of unitarity for

$$W_{L}$$
 χ
 χ
 W_{L}

$$\mathcal{M} = \frac{s}{v^2} - \frac{G_V^2}{v^4} \left[3s + m_V^2 \left(\frac{s - u}{t - m_V^2} + \frac{s - t}{u - m_V^2} \right) \right]$$

The unitarity constraint is almost insensitive to the value m_V

EWPO

Barbieri et al. [0806.1624]

Cata & J.F.K [1006.xxxx]

The leading contributions to S & T generated by the exchange of single heavy fields

$$\Delta \hat{S} = g^2 \left(\frac{F_V^2}{4m_V^2} - \frac{F_A^2}{4m_A^2} \right) + \frac{g^2}{6} \frac{\Lambda^2}{(4\pi v)^2} \left[-\left(\frac{F_V - 2G_V}{2m_V} \right)^2 + \left(\frac{F_A}{2m_A} \right)^2 - \frac{v^2}{m_V^2} - \frac{v^2}{m_A^2} \right] + \dots$$

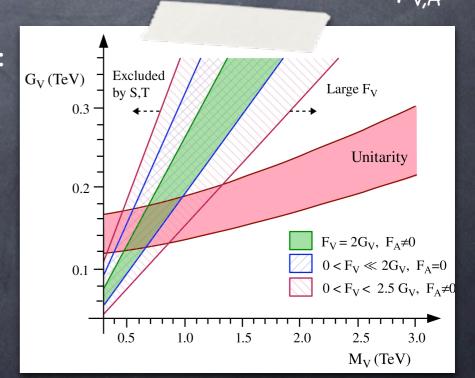

$$\hat{S} = g^2 \left(\frac{F_V^2}{4m_V^2} - \frac{F_A^2}{4m_A^2} \right) + \frac{g^2}{6} \frac{\Lambda^2}{(4\pi v)^2} \left[-\left(\frac{F_V - 2G_V}{2m_V} \right)^2 + \left(\frac{F_A}{2m_A} \right)^2 - \frac{v^2}{m_V^2} - \frac{v^2}{m_A^2} \right] + \dots$$

$$\Delta \hat{T} = \frac{3\pi\alpha}{c_W^2} \left[\frac{F_A^2}{4m_A^2} + \left(\frac{F_V - 2G_V}{2m_V} \right)^2 \right] \frac{\Lambda^2}{16\pi^2 v^2} + \dots \quad \text{O(1) factors [Λ replaced by some heavy mass]}$$

- Both V and A light, almost degenerate
- Only V light, with small F_V
- EWPO & unitarity can be accommodated for specific choices of the free parameters

Main conclusion: We need at least one relatively light vector field

- Main properties of vector fields
 - Leading decay mode: 2 longitudinal SM gauge bosons

$$\Gamma_{V^+} \approx \Gamma_{WZ}^V = \frac{G_V^2 m_V^3}{48\pi v^4} \left[1 + \mathcal{O}(g^2 \epsilon^2) \right] \; , \qquad \text{5 GeV [m_V = 0.5 TeV]}$$

$$40 \; \text{GeV [m_V = 1.0 TeV]}$$

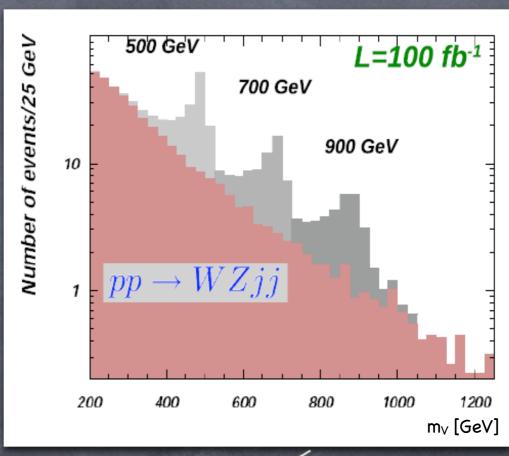

$$\Gamma_{V^0} \approx \Gamma_{WW}^V = \Gamma_{WZ}^V \left[1 + \mathcal{O}(g^2 \epsilon^2) \right]$$

- Narrow widths!
- ZZ channel forbidden
- Coupling to SM fermions highly suppressed

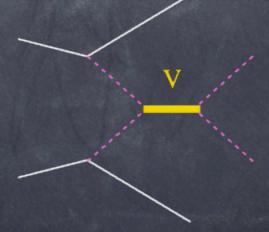

$$Br(V^0 \to q \bar{q}) \approx 3 Br(V^0 \to \ell^+ \ell^-) \approx \frac{6 F_V^2 m_W^4}{G_V^2 m_V^4} \quad \text{1.6\% [m_V = 0.5 TeV, F_V = 2G_V]}$$

Leading decay modes of <u>axial</u> fields can be to a vector and SM g. b.

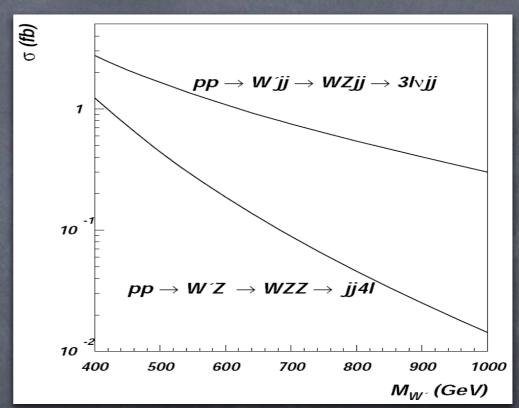

- The most general signature of Higgsless models is the appearance of the vector state in WW scattering [pp → V + jj (WW fusion) → WW(WZ) + jj]
- Model-independent link with the unitarity problem

Belyaev [0711.1919]

- The most general signature of Higgsless models is the appearance of the vector state in WW scattering [pp → V + jj (WW fusion) → WW(WZ) + jj]
- A difficult analysis, which requires high statistics.

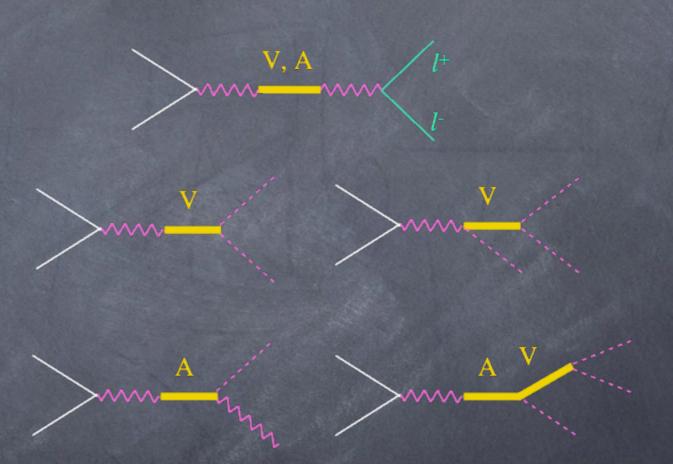

Belyaev [0711.1919]

Resonant cross section including

- leptonic BR's (l=e, μ) [$\epsilon_{lept} = 21\% \times 6.7\% = 1.5\%$]
- p_T(jets) > 30 GeV
- standard VBF jet cuts $[\Delta \eta > 4, M_{jj} > 1 \text{TeV} \epsilon_{VBF} < 30\%]$

- A potentially cleaner signal (if the resonances are not too heavy) is the Drell-Yan production of the resonances and subsequent decay into l⁺l⁻, 2 and 3 SM heavy gauge bosons
 - Link to the contribution of the heavy vectors to EPWO

Given the narrow widths, for low masses the signals are quite large

update of Cata, Isidori & J.F.K [0905.0490] using Fv² = 4Gv² = 4v²/3

	M = 500 GeV	M = 750 GeV	M = 1000 GeV
$\sigma(pp \to V^+ \to X)_{\sqrt{s}=14 \text{ TeV}}$	11 pb	$1.2~\mathrm{pb}$	$0.23~\mathrm{pb}$
$\sigma(pp \to V^+ \to X)_{\sqrt{s}=10 \text{ TeV}}$	6.7 pb	0.71 pb	0.13 pb
$\sigma(pp \to V^+ \to X)_{\sqrt{s}=7 \text{ TeV}}$	4.2 pb	0.32 pb	0.06 pb

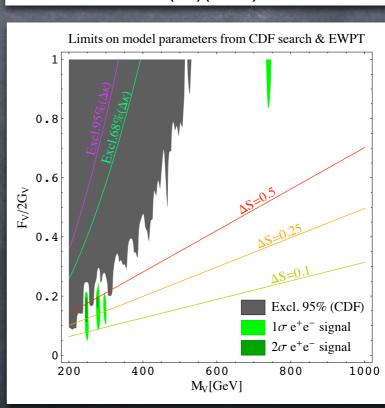

- However....
 - The leading decay modes (2W, 3W) have low efficiencies
 - The l^+l^- case is suppressed by the small $Br(R \rightarrow l^+l^-)$

Signal of heavy vectors at the Tevatron?

- The l⁺l⁻ state of the art are the analyses of the e⁺e⁻ and µ⁺µ⁻ final states in p-pbar collisions published by CDF & DO
- Using data as normalization for the SM events (takes into account all the relevant exp. efficiencies!), one can produce an exclusion plot in the F_V-m_V plane complementary to EWPT bounds
- Two main assumptions:

 - m_A >> m_V

CDF [0810.2059] [0811.0053] Publ. 10165

DO Conf. Note 5923

See talk by Wittich

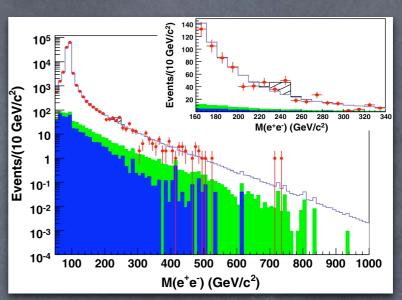

Cata, Isidori & J.F.K [0905.0490]

Signal of heavy vectors at the Tevatron?

The l⁺l⁻ state of the art are the analyses of the e⁺e⁻ and μ⁺μ⁻ final states in p-pbar collisions published by CDF & DO

If, on the other hand, the excess at higher mass will become significant, we can hope to see a clear signal at the LHC (even with 1-2 fb⁻¹ @ 14TeV)

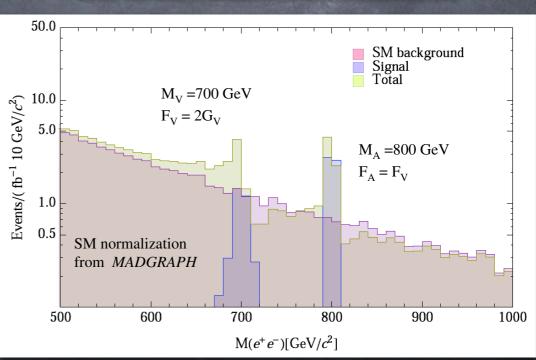

Analysis of prospects for 1fb⁻¹ @ 7TeV in progress Not huge peaks as with a sequential Z', but they should be clearly visible.

CDF [0810.2059] [0811.0053] Publ. 10165

DO Conf. Note 5923

See talk by Wittich

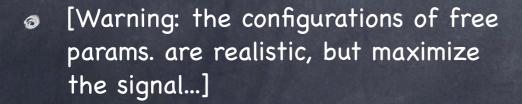

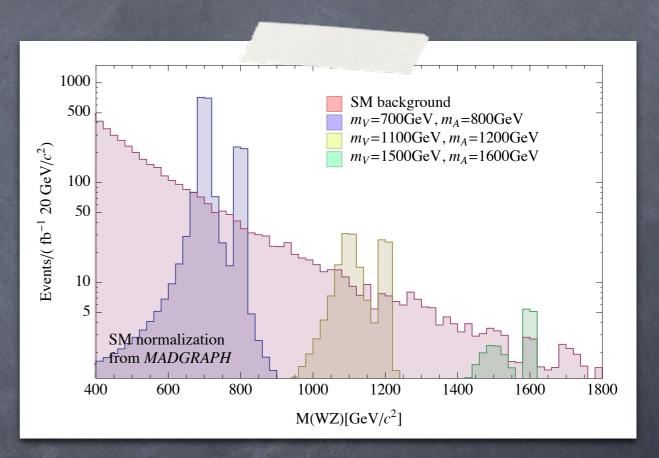

Signals for heavy vectors at the LHC

- Two SM gauge boson final states
- Some illustrative examples

$$\odot$$
 [WZ] BrZ_{lept} \times BrW_{lept} = 1.5 %

- \bullet $F_V = 2G_V$
- $F_A = F_V$
- G_V fixed by unitarity

See also He et al. [0708.2588]

Accomando et al. [0807.5051, 0807.2951]

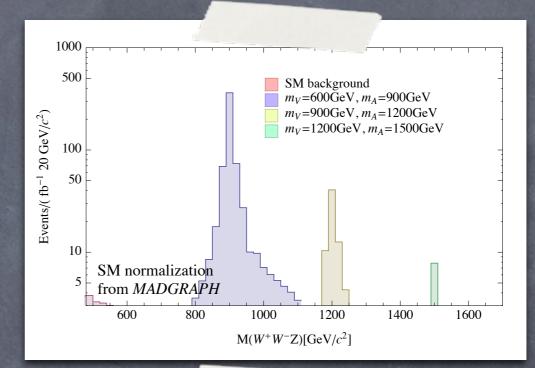

Belyaev et al. [0809.0793]

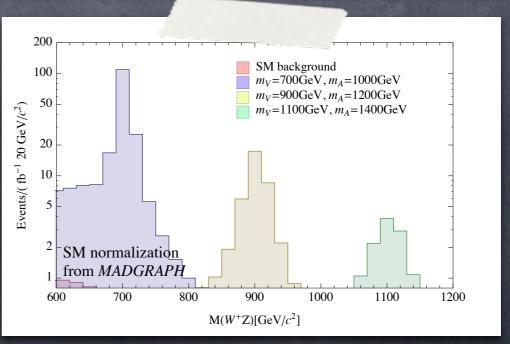

Signals for heavy vectors at the LHC

- Three SM gauge boson final states
- Some illustrative examples
 - [WWZ] $BrZ_{lept} \times BrW_{lept} \times$ $BrW_{had} = 0.9 \%$
 - \bullet $F_V = 2G_V$
 - \bullet $F_A = F_V$

 - $g_A = 1/2$
- In the WWZ final state it is also worth to look at the WZ invariantmass distribution

Conclusions

- Heavy vector fields, which replace the Higgs boson in maintaining perturbative unitarity up to LHC energies, are naturally expected in a wide class of Higgsless models.
- The most general signature of these models is the appearance of the lightest vector state in WW scattering (model-independent link with the unitarity problem).
- The Drell-Yan production of the new states is subject to larger uncertainties.

Se also Barbieri et al [0911.1942]

- For light m_{V(A)} we could expect visible signals (even with low statistics), and the information could help to clarify the role of the heavy vectors in EWPO.
- The results in the e^+e^- and $\mu^-\mu^+$ channels from Tevatron are already providing significant information.
- The 2 and 3 SM gauge boson final states seems to be quite promising and a more realistic study is in progress.

EWPO in the SM

Peskin & Takeuchi [PRL65:964,1990] Altarelli & Barbieri [PLB253:161,1991]

Barbieri et al. [hep-ph/0405040]

- Some dynamical sensitivity to the Higgs mechanims is obtained from EWPO
- Indirect indication of a light m_H under the hypothesis of a heavy cut-off for the SM as effective theory
 - (<-> fine tuning in the Higgs mass term)

$$T = \frac{\Pi_{33}(0) - \Pi_{WW}(0)}{m_W^2}$$

$$S = \frac{g}{g'} \frac{d\Pi_{30}(q^2)}{dq^2} \Big|_{q^2=0}$$

- With heavy spin-1 fields, there is a peculiar problem related to the possible mixing of the heavy states and the Goldstone bosons.
 - Describing the heavy states in terms of Lorentz vectors $(V_{\mu} \& A_{\mu})$, we have a possible mass-mixing of $O(p) \ [\rightarrow tedious redefinition of the fields]$

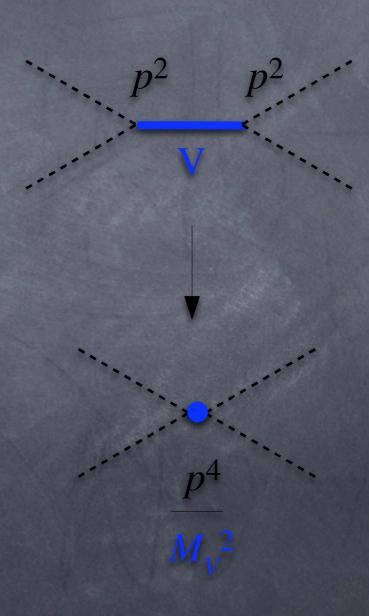

Gasser & Leutwyler [Annals Phys.158:142,1984] Ecker et al. [Phys.Lett.B223:425,1989] This problem can be avoided describing the heavy spin-1 states by means of antisymmetric tensors ($R_{\mu\nu}$ = $V_{\mu\nu}$, $A_{\mu\nu}$):

$$\mathcal{L}_{kin}(R^{\mu\nu}) = -\frac{1}{2} \text{Tr}(\nabla_{\mu} R^{\mu\nu} \nabla^{\sigma} R_{\sigma\nu}) + \frac{1}{4} m_R^2 \text{Tr}(R^{\mu\nu} R_{\mu\nu})$$

$$\langle 0 | R^{\mu\nu} | R(p, \epsilon) \rangle = \frac{i}{m_R} [p_{\mu} \epsilon_{\nu} - p_{\nu} \epsilon_{\mu}]$$

$$\nabla_{\mu} R = \partial_{\mu} R + [\Gamma_{\mu}, R] \qquad \Gamma_{\mu} = \frac{1}{2} [u^{\dagger} D_{\mu} u + u D_{\mu} u^{\dagger}], \quad u^2 = U$$

- In the antisymmetric formulation the couplings between heavy fields and Goldstone bosons start at O(p²) ⇒ integrating out the heavy fields we are automatically projected into the basis of the O(p⁴) chiral operators with light fields only.
 - In QCD case this procedure leads to a successful description of all the leading O (p⁴) light-field couplings
- 1⇔1 correspondence between
 lowest-order vector couplings [O (p²)] and next-to-leading order Goldstone-boson couplings [O(p⁴)]

- The dynamics of the system below the cut-off is described by 3 + 2 parameters: $(M_V, G_V, F_V) + (M_A, F_A)$.
 - Naive dimensional analysis implies $F_{V(A)}$, $G_V = O(v)$

$$[u_{\mu} = iu^{\dagger}D_{\mu}Uu^{\dagger}] \qquad \mathcal{L}_{int} = \frac{i}{2\sqrt{2}}G_{V}\mathrm{Tr}(V^{\mu\nu}[u_{\mu}, u_{\nu}]) \qquad \qquad W_{L} \qquad W$$

Specific UV completions of this effective theory correspond to specific choices of the free parameters.

- Main properties of axial fields
 - $O(m_A^3)$ widths only from $A \rightarrow VW$
 - [mediated by effective ops. with two heavy fields $A[\partial V, \partial U]$, not included in Lint]
 - potentially suppressed if m_A ≈ m_V

$$\bullet \quad \Gamma^{A}_{V^{+}W^{-}} = \Gamma^{A}_{V^{-}W^{+}} = \Gamma^{A}_{V^{-}W^{+}} = \Gamma^{A}_{V^{+}Z} \doteq \Gamma^{A}_{VW} \,,$$

$$\Gamma_{V^+W^-}^A = \Gamma_{V^-W^+}^A = \Gamma_{V^0W^+}^A = \Gamma_{V^+Z}^A \doteq \Gamma_{VW}^A \,,$$

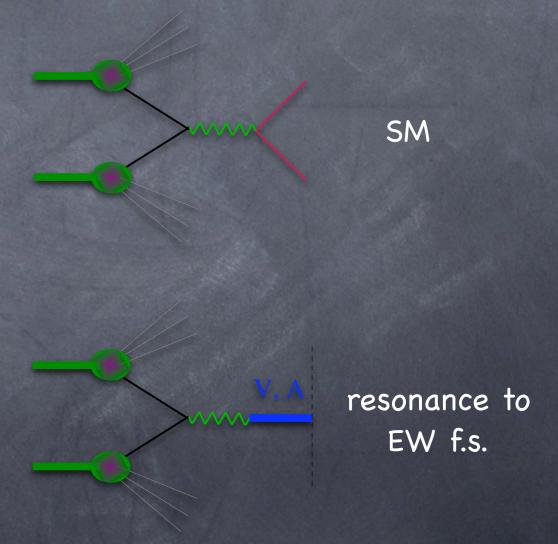

$$\Gamma_{VW}^A = \frac{m_A^3}{48\pi v^2} (1-r^2)^3 \left[g_A^2 (1+2r^2) + g_V^2 \left(1+\frac{2}{r^2}\right) + 6g_A g_V \right]$$

 $O(m_A)$ widhts of the type A \rightarrow longitudinal + transverse SM gauge bosons,

$$\Gamma_{WW}^{A} = \frac{g^2 F_A^2 m_A}{192 \pi v^2} \; , \quad \Gamma_{WZ}^{A} = \frac{1}{2} \Gamma_{WW}^{A} \left[1 + \frac{(1 - 2s_W^2)^2}{c_W^2} \right] \; , \quad \Gamma_{W\gamma}^{A} = 2s_W^2 \; \Gamma_{WW}^{A}$$

- leading decay modes if m_A ≈ m_V
- Decay widhts to SM fermions identical to the vector case, with corresponding BR enhanced by the suppression of the total rate

- A potentially clean signal (if the resonances are not too heavy) is the Drell-Yan production of the resonances and subsequent decay into l⁺l⁻, 2 and 3 SM heavy gauge bosons
 - easy to estimate (and simulate) normalizing the non- standard rate to SM Drell-Yan processes at the partonic level

Cata, Isidori & J.F.K [0905.0490]

E.g. for charged final states we define the form factor

$$F_f^{R^+}(q^2) = \frac{\sigma(u\bar{d} \to R^+ \to f)}{\sigma(u\bar{d} \to \mu^+ \nu)_{\text{SM}}}$$

$$\frac{d}{dq^2}\sigma(pp \to R^+ \to f) = F_f^{R^+}(q^2)\frac{d}{dq^2}\sigma(pp \to \mu^+ \nu)_{\text{SM}}$$

As long as we can neglect interference effects (with SM or among different resonant contributions), the partonic resonant width is simply given by

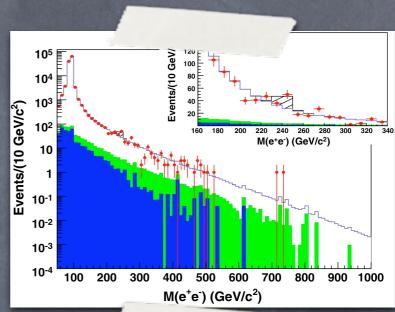

$$\sigma(q_i \bar{q}_j \to R \to f) = \frac{12\pi \Gamma_R^2 B r_{\text{in}}^R B r_f^R}{(q^2 - m_R^2)^2 + m_R^2 \Gamma_R^2} \left[1 + \mathcal{O}\left(\frac{q^2 - m_R^2}{m_R^2}\right) \right]$$

Signal of heavy vectors at the Tevatron?

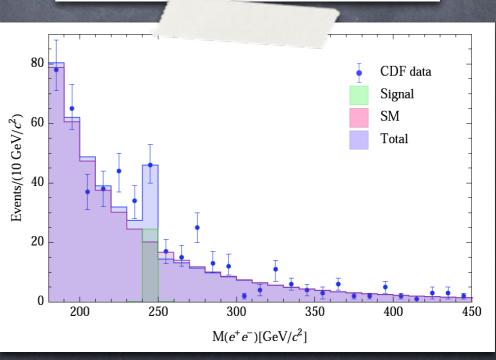

- The I⁺I⁻ state of the art is the analysis of the e⁺e⁻ final state in p-pbar collisions published by CDF
- The "2σ excess" can be fitted nicely by a light vector resonance:
 - m_∨ ≈ 246 GeV
 - F_V ≈ 50 GeV
- Predictions derived within the effective theory:

excluded by CDF [0811.0053]

- similar peak also in the μ⁺μ⁻
 final state
- axial state with $m_A \approx 1.3$ TeV to obtain a good EWPO fit

CDF [0810.2059]

Signals for heavy vectors at the LHC

- Two & three SM gauge boson final states
- A detailed estimate of the realistic efficiency for the detection of the heavy vectors in these final states [WZ, WW] + [WWW, WWZ, WZZ] has not been performed yet. So far we have analysed only the signal against the irreducible SM background = same e.w. final state
- Selecting leptonic decay is a high price to pay (in terms of efficiencies), but it should ensure a good rejection against non-irreducible backgrounds.
 - Some reference theoretical efficiencies:
 - \odot [WZ] BrZ_{lept} \times BrW_{lept} = 1.5 %
 - [WWZ] $BrZ_{lept} \times BrW_{lept} \times BrW_{had} = 0.9 \%$
 - [WZZ] $BrZ_{lept} \times BrW_{lept} \times BrZ_{had} = 1 \%$
 - [WZZ] $(BrZ_{lept})^3 \times BrZ_{had} = 0.4 \%$
 - [WWW] $(BrW_{lept})^3 = 1\%$

Signals for heavy vectors at the LHC

- In the WWZ final state it is also worth to look at the WZ invariant-mass distribution
 - With high statistics (100 fb⁻¹), here we can hope to see a signal even without a light axial vector
