## Outline

- Introduction
- Cubic vertices for massless fields in any dimensions
- Cubic vertices in $d=3$
- Implications for 2d CFT
- Conclusions

## Introduction

- Vasiliev equations in $(A) d S_{d}(d \geq 3)$ describe interacting theory of infinite tower of massless fields with spins
$s=0,1,2,3, \ldots$, while action formulation is not known.
- Free action is available and cubic vertices are classified in any $d \geq 4$ (first step of the so-called Fronsdal program).
- In $d=3$, an action formulation exists for both $A d S$ and flat HS gravity, without matter (Chern-Simons). Matter-coupled Prokushkin-Vasiliev eq.'s lack action formulation though.
- Fronsdal program in $d=3$ provides a way to couple matter to HS fields and construct action for Prokushkin-Vasiliev theory.

## To quote Edward Witten (Strings 2017)

... Even when we have what seem like simple toy models of holography such as the dual of Vasiliev theory, or the SYK model, we have only a hazy idea of the bulk physics.
... One way or another, we are in need of something - new bulk descriptions or possibly a better understanding of why it is difficult to find them and what sort of things one should be looking for.

## Reformulation in my language

I admit that despite of many impressive achievements in recent years, we still have little progress in the old problem of classical action formulation for candidate Quantum Gravity theories. This core problem needs to be resolved to allow for progress in Quantum Gravity.

## Formalism

Spin- $s$ massless field is described by a rank-s symmetric tensor

$$
\varphi^{(s)}(a, x)=\frac{1}{s!} \varphi_{\mu_{1} \ldots \mu_{s}} a^{\mu_{1}} \cdots a^{\mu_{s}}
$$

where $a^{\mu}$ is an auxiliary vector, useful for handling arbitrary spin tensors. For example, divergence and trace are given as:

$$
\begin{array}{r}
\left(\partial \cdot \partial_{a}\right) \varphi^{(s)}(a, x)=\frac{1}{(s-1)!} \partial^{\nu} \varphi_{\nu \mu_{2} \ldots \mu_{s}} a^{\mu_{2}} \cdots a^{\mu_{s}} \\
\quad \square_{a} \varphi^{(s)}(a, x)=\frac{1}{(s-2)!} \varphi^{\nu}{ }_{\nu \mu_{3} \ldots \mu_{s}} a^{\mu_{3}} \cdots a^{\mu_{s}} .
\end{array}
$$

Here, $\partial_{\mu}=\frac{\partial}{\partial x^{\mu}}, \partial_{\mu}^{a}=\frac{\partial}{\partial a^{\mu}}$.

## Free theory

Free action is given as

$$
S=\frac{1}{2} \int d^{d} x \varphi^{(s) \mu_{1} \ldots \mu_{s}} \square \varphi_{\mu_{1} \ldots \mu_{s}}^{(s)}+\ldots
$$

and free equations of motion are given by Fronsdal tensor, $\mathcal{F}^{(s)}=0$

$$
\mathcal{F}_{\mu_{1} \ldots \mu_{s}}^{(s)}=\square \varphi_{\mu_{1} \ldots \mu_{s}}^{(s)}+\ldots,
$$

linearised Einstein-Hilbert (Fierz-Pauli) action for $s=2$.
There is a gauge symmetry with transformation law:
$\delta \varphi_{\mu_{1} \ldots \mu_{s}}^{(s)}=\partial_{\left(\mu_{1}\right.} \epsilon_{\left.\mu_{2} \ldots \mu_{s}\right)}^{(s-1)}, \quad \epsilon^{(s-1)}(x, a)=\frac{1}{(s-1)!} \epsilon_{\mu_{1} \ldots \mu_{s-1}} a^{\mu_{1}} \cdots a^{\mu_{s-1}}$.
Constraints: $\square_{a} \epsilon^{(s-1)}(a, x)=0, \square_{a}^{2} \varphi^{(s)}(a, x)=0$.

## Interactions via Noether Method

Expand the action and gauge transformations in powers of fields:

$$
\begin{aligned}
S[\varphi] & =S_{2}[\varphi]+g S_{3}[\varphi]+g^{2} S_{4}[\varphi]+\ldots \\
\delta \varphi & =\delta^{0} \varphi+g \delta^{1} \varphi+g^{2} \delta^{2} \varphi+\ldots
\end{aligned}
$$

The full action is gauge invariant: $\delta S[\varphi]=0$, which implies:

$$
\begin{aligned}
\delta^{0} S_{2}[\varphi] & =0, \\
g\left(\delta^{1} S_{2}[\varphi]+\delta^{0} S_{3}[\varphi]\right) & =0, \\
g^{2}\left(\delta^{2} S_{2}[\varphi]+\delta^{1} S_{3}[\varphi]+\delta^{0} S_{4}[\varphi]\right) & =0,
\end{aligned}
$$

The solution to the first equation, i.e. the free action $S_{2}[\varphi]$ and $\delta^{0} \varphi$, are known.

## Noether method at work

Cubic order in the action, $S_{3}[\varphi]$, satisfies the equation

$$
\delta^{1} S_{2}[\varphi]+\delta^{0} S_{3}[\varphi]=0
$$

Taking into account, that $\delta S_{2} \approx 0$ (for any $\delta \varphi$ ), where $\approx$ means equivalence up to free equations of motion, we are led to

$$
\delta^{0} S_{3}[\varphi] \approx 0
$$

The cubic order Lagrangian can be written in the form

$$
\mathcal{L}^{(3)}=\sum_{\left\{s_{i}\right\}, n} g_{s_{1}, s_{2}, s_{3}}^{n} \mathcal{L}_{s_{1}, s_{2}, s_{3}}^{n},
$$

$n$ counts independent vertices for three fields with arbitrary spins:

$$
\mathcal{L}_{s_{1}, s_{2}, s_{3}}^{n}=\mathcal{V}_{s_{1}, s_{2}, s_{3}}^{n}\left(\partial_{a_{i}}, \partial_{i}\right) \varphi^{\left(s_{1}\right)}\left(a_{1}, x_{1}\right) \varphi^{\left(s_{2}\right)}\left(a_{2}, x_{2}\right) \varphi^{\left(s_{3}\right)}\left(a_{3}, x_{3}\right)
$$

## Vertex operator algebra

A basis of building blocks for the vertex operators are given in our language (we discard total derivatives)

$$
\begin{array}{r}
B_{i j}=\partial_{i} \cdot \partial_{j}, \quad y_{i}=\partial_{a_{i}} \cdot \partial_{i+1}, \quad z_{i}=\partial_{a_{i+1}} \cdot \partial_{a_{i-1}} \\
D_{i v_{i}}=\partial_{a_{i}} \cdot \partial_{i}, \quad T r_{i} \equiv \square_{a_{i}}=\partial_{a_{i}} \cdot \partial_{a_{i}}
\end{array}
$$

- We restrict ourselves for simplicity to Traceless-Transverse part of the vertex, discarding $\operatorname{Div}_{i}$ and $T r_{i}$ operators.
- We discard total derivatives and fix field redefinition freedom uniquely so that there are no operators $B_{i j}$ in the vertex.

## Simplification

The traceless-transverse part of the cubic vertex for arbitrary spin massless bosons depends only on six structures $y_{i}, z_{i}$ : $\mathcal{V}\left(y_{i}, z_{i}\right)$.

## Cubic vertices in any $d \geq 4$

Using commutators $\left[y_{i}, a_{j} \cdot \partial_{j}\right] \approx 0,\left[z_{i \pm 1}, a_{i} \cdot \partial_{i}\right] \approx \pm y_{i \neq 1}$, the equation $\delta^{0} \mathcal{L}^{(3)} \approx 0$ is reformulated as:

$$
\left(y_{i-1} \partial_{z_{i+1}}-y_{i+1} \partial_{z_{i-1}}\right) \mathcal{V}\left(y_{i}, z_{i}\right) \approx 0
$$

The solution is simple:

$$
\mathcal{V}\left(y_{i}, z_{i}\right)=C\left(y_{i}, G\right), \quad G=y_{1} z_{1}+y_{2} z_{2}+y_{3} z_{3}
$$

$\mathcal{V}_{s_{1}, s_{2}, s_{3}}^{n}$ vertex with $s_{1}+s_{2}+s_{3}-2 n \geq \max \left\{s_{i}\right\}$ derivatives

$$
\mathcal{V}_{s_{1}, s_{2}, s_{3}}^{n}\left(y_{i}, z_{i}\right)=y_{1}^{s_{1}-n} y_{2}^{s_{2}-n} y_{3}^{s_{3}-n} G^{n}, \quad\left(0 \leq n \leq \min \left\{s_{i}\right\}\right)
$$

One vertex for each number of derivatives in the allowed range. Altogether $\min \left\{s_{1}, s_{2}, s_{3}\right\}+1$ vertices. Matches the structures of three-point functions of conserved currents in $C F T_{d-1}$.

## Cubic vertices in $d \geq 3$ : examples

Pure spin-one vertices:

$$
\begin{array}{lc}
\mathcal{V}_{1,1,1}^{0}=y_{1} y_{2} y_{3} & \left(F^{3} \text { vertex }\right) \\
\mathcal{V}_{1,1,1}^{1}=G & \text { (Yang-Mills vertex) }
\end{array}
$$

## Pure spin-two vertices:

$$
\begin{aligned}
& \mathcal{V}_{2,2,2}^{0}=y_{1}^{2} y_{2}^{2} y_{3}^{2} \\
& \mathcal{V}_{2,2,2}^{1}=y_{1} y_{2} y_{3} G \\
& \mathcal{V}_{2,2,2}^{2}=G^{2}
\end{aligned}
$$

( $W^{3}$ vertex).
(Gauss-Bonnet vertex).
(Einstein-Hilbert vertex).

## Cubic vertices in $d=3$

In 3d, the construction gets modified by Schouten identities (SI), i.e. operators, contracting $\delta_{\mu_{1} \mu_{2} \mu_{3} \mu_{4}}^{\nu_{1} \nu_{2} \nu_{3} \nu_{4}}$ and $\partial_{a_{i}}^{\mu}, \partial_{i}^{\nu}$ operators.

$$
\left(y_{i-1} \partial_{z_{i+1}}-y_{i+1} \partial_{z_{i-1}}\right) \mathcal{V}\left(y_{i}, z_{i}\right) \approx S I \equiv 0
$$

The list of elementary Schouten identities, relevant to the cubic vertex problem is given as (no summation over $i$ ):

$$
\begin{aligned}
\left(G-y_{i} z_{i}\right)^{2} & =0, & y_{i} z_{i} G-y_{i-1} z_{i-1} y_{i+1} z_{i+1}=0, \\
y_{i} y_{i \pm 1}\left(G-y_{i} z_{i}\right) & =0, & \\
y_{i}^{2} y_{i+1}^{2} & =0, & y_{i}^{2} y_{i+1} y_{i-1}=0 .
\end{aligned}
$$

Due to these identities, the classification of three dimensional vertices is different from $d \geq 4$.

## Cubic vertices in 3d: massless scalar and vector fields

For simplicity, we assume $s_{1} \geq s_{2} \geq s_{3}$ and derive the parity-even vertices only. All the vertices with scalar fields $\left(s_{3}=0\right)$ are:

$$
\begin{aligned}
& \mathcal{V}_{s, 0,0}=y_{1}^{s} \\
& \mathcal{V}_{s, 1,0}=y_{1}^{s} y_{2}
\end{aligned}
$$

while all the vertices with Maxwell vector fields $\left(s_{3}=1\right)$ are:

$$
\begin{aligned}
& \mathcal{V}_{s, 1,1}=y_{1}^{s-1} G \\
& \mathcal{V}_{s, s, 1}=y_{1} y_{2} y_{3} z_{3}^{s-1}
\end{aligned}
$$

The only example of spin configurations in three dimensions, with more than one vertex, is $s_{1}=s_{2}=s_{3}=1$ :

$$
\mathcal{V}_{1,1,1}^{Y M}=G, \quad \mathcal{V}_{1,1,1}^{F^{3}}=y_{1} y_{2} y_{3}
$$

## Cubic vertices in 3d: gravitational coupling

Massless spin two interactions ( $s_{3}=2$ ) are interesting as in three dimensions one can have minimal coupling to gravity:

$$
\mathcal{V}_{s, s, 2}=y_{3} z_{3}^{s-1}\left(s y_{1} z_{1}+s y_{2} z_{2}+y_{3} z_{3}\right)
$$

This vertex could be also derived by simply covariantising derivatives in massless spin-s free action.
It does not spoil gauge invariance of spin-s field only in three dimensions due to triviality of Weyl tensor, which implies that the Riemann tensor is algebraically related to Ricci tensor - equation of motion for metric.
This naturally triggers the possibility to have a minimal coupling to gravity, at the expense of deforming the gauge transformation of the metric and enlarging the space-time symmetries exactly in the same way as introducing massless spin $\frac{3}{2}$ field leads to SUGRA.

## Cubic vertices in 3d: general triples $s_{1} \geq s_{2} \geq s_{3} \geq 2$

## $s_{1} \geq s_{2}+s_{3}$.

No vertices!
$s_{1}<s_{2}+s_{3}$. Two cases:
$s_{1}+s_{2}+s_{3}$ is even. There is a unique two-derivative vertex:
$\mathcal{V}_{s_{1}, s_{2}, s_{3}}=\left[\left(s_{1}-1\right) y_{1} z_{1}+\left(s_{2}-1\right) y_{2} z_{2}+\left(s_{3}-1\right) y_{3} z_{3}\right] G z_{1}^{n_{1}} z_{2}^{n_{2}} z_{3}^{n_{3}}$

$$
n_{i}=\frac{1}{2}\left(s_{i-1}+s_{i+1}-s_{i}\right)-1 \geq 0 .
$$

$s_{1}+s_{2}+s_{3}$ is odd. There is a unique three-derivative vertex:

$$
\begin{gathered}
\mathcal{V}_{s_{1}, s_{2}, s_{3}}=y_{1} y_{2} y_{3} z_{1}^{n_{1}} z_{2}^{n_{2}} z_{3}^{n_{3}}, \\
n_{i}=\frac{1}{2}\left(s_{i-1}+s_{i+1}-s_{i}-1\right) \geq 0
\end{gathered}
$$

## Cubic vertices in 3d: parity-odd case for $s_{1} \geq s_{2} \geq s_{3} \geq 2$

$s_{1} \geq s_{2}+s_{3}$.
No vertices!
$s_{1}<s_{2}+s_{3}$. Two cases:
$s_{1}+s_{2}+s_{3}$ is odd. There is a unique two-derivative vertex:

$$
\begin{gathered}
\mathcal{V}_{s_{1}, s_{2}, s_{3}}^{P O}=\left[n_{1} W_{1} z_{1}+n_{2} W_{2} z_{2}+n_{3} W_{3} z_{3}\right] z_{1}^{n_{1}} z_{2}^{n_{2}} z_{3}^{n_{3}} \\
W_{i}=\epsilon^{\mu \nu \lambda} \partial_{\mu}^{a_{i}} \partial_{\nu}^{i+1} \partial_{\lambda}^{i-1}, \quad n_{i}=\frac{1}{2}\left(s_{i-1}+s_{i+1}-s_{i}-1\right) \geq 0
\end{gathered}
$$

$s_{1}+s_{2}+s_{3}$ is even. There is a unique three-derivative vertex:

$$
\begin{array}{r}
\mathcal{V}_{s_{1}, s_{2}, s_{3}}=y_{1} y_{2} y_{3} U z_{1}^{n_{1}} z_{2}^{n_{2}} z_{3}^{n_{3}} \\
U=\epsilon^{\mu \nu \lambda} \partial_{\mu}^{a_{1}} \partial_{\nu}^{a_{2}} \partial_{\lambda}^{a_{3}}, \quad n_{i}=\frac{1}{2}\left(s_{i-1}+s_{i+1}-s_{i}\right)-1 \geq 0
\end{array}
$$

## Cubic vertices in 3d: parity-odd vs parity-even

## Key observation:

$U^{2}=-2 z_{1} z_{2} z_{3} \rightarrow z_{1}^{1 / 2} z_{2}^{1 / 2} z_{3}^{1 / 2}=\frac{i}{\sqrt{2}} U$
In the two-derivative parity-odd vertex perform the substitution $n_{i} \rightarrow n_{i}+\frac{1}{2}$ (and use that $\left.W_{i} U=y_{i}\left(G-y_{i} z_{i}\right)\right)$

$$
\begin{aligned}
\mathcal{V}_{s_{1}, s_{2}, s_{3}}^{P O} \rightarrow\left[\left(n_{1}+\frac{1}{2}\right) W_{1} z_{1}+\left(n_{2}+\frac{1}{2}\right) W_{2} z_{2}\right. & \left.+\left(n_{3}+\frac{1}{2}\right) W_{3} z_{3}\right] \\
& \times \frac{i}{\sqrt{2}} U z_{1}^{n_{1}} z_{2}^{n_{2}} z_{3}^{n_{3}} \\
=\frac{i}{\sqrt{2}}\left[s_{1} y_{1} z_{1}+s_{2} y_{2} z_{2}+s_{3} y_{3} z_{3}\right] G z_{1}^{n_{1}} z_{2}^{n_{2}} z_{3}^{n_{3}} & =\mathcal{V}_{s_{1}+1, s_{2}+1, s_{3}+1} .
\end{aligned}
$$

## Conclusion:

Parity-even and parity-odd vertices are related by half-integer shift of exponents of $z_{i}$ (or $s_{i} \rightarrow s_{i}+1$ ), and the above replacement. Remarkable example of analiticity in spin!

## Cubic vertices in 3d: Chern-Simons couplings

## Minimal coupling to CS vector field for any spin-s field

Direct computation shows that there is a minimal coupling $(s, s, 1)$ with one derivative, given as:

$$
\mathcal{V}_{\mathcal{C S}}=y_{3} z_{3}^{s}
$$

## Alternative derivation:

Let us take the free action of a spin-s field and replace derivatives with covariant ones $\partial_{\mu} \rightarrow \nabla_{\mu}=\partial_{\mu}+A_{\mu}$. The obstruction terms for spin-s gauge invariance are related to commutators $\left[\nabla_{\mu}, \nabla_{\nu}\right]=$ $F_{\mu \nu}$. These are CS equations of motion!

## Conclusion:

CS minimal coupling works exactly same way as minimal coupling to gravity. CS field gets deformation of gauge transformation via gauge parameter of the spin-s field.

More vertices with CS fields. See arXiv:1803.02737 for the full list.

## Cubic vertices in 3d: beyond Minkowski

## This classification extends to arbitrary Einstein background.

In full theory, Einstein eq.'s get corrections quadratic in HS fields.
Einstein spaces are still solutions of the whole system, with zero background values of HS fields. We can expand around these solutions, and the cubic vertices can be extended straightforwardly.

## Know how.

One can simply replace $\partial \rightarrow \nabla$, to get the vertex in arbitrary Einstein spaces, treating gravity in full non-linear manner, while still expanding in powers of HS (weak) fields.

## Cubic vertices in $A d S_{3}$ vs 3pt functions in $C F T_{2}$

## Match to CFT

For $s_{1} \geq s_{2} \geq s_{3} \geq 2$ and $s_{1}<s_{2}+s_{3}$ we have one-to-one match of the number of cubic vertices in $A d S_{3}$ and independent structures in 3pt functions of conserved currents on the boundary.
There are two vertices for every triple - one parity-even and one parity-odd.
There are two independent structures in three-point functions chiral and anti-chiral.

Puzzle
The absence of the vertices for $s_{1} \geq s_{2}+s_{3}$ is puzzling as there are structures of 3pt functions in $\mathrm{CFT}_{2}$, corresponding to such vertices.

## Resolution coming soon

The resolution of this puzzle is a work in progress (in collaboration with Stefan Fredenhagen and Olaf Krüger).

## Conclusions

## Main Points

- Exhaustive classification of cubic vertices for massless bosons in three dimensions. Minimal coupling to gravity and Chern-Simons vector fields as particular examples.
- As opposed to $d \geq 4$, there is at most one parity-even and one parity-odd vertex for each triple of spins (with one exception),
- They can be extended to arbitrary Einstein background, and match CFT 3pt functions wherever applicable.
- Relation between parity-even and parity-odd vertices.
- A non-trivial model-independent property of any $C F T_{2}$ with HS conserved currents uncovered.
- This is the first step towards Lagrangian theories of HS fields with matter in $d=3$.

## Additional slides follow

## Free theory

Free action is given as

$$
S=\frac{1}{2} \int d^{d} x \varphi^{(s)}(a, x) \star\left[1-\frac{1}{4} a^{2} \square_{a}\right] \mathcal{F}^{(s)}(a, x),
$$

and free equations of motion are given by Fronsdal tensor, $\mathcal{F}^{(s)}=0$

$$
\mathcal{F}^{(s)}(a, x)=\left[\square-\left(a \cdot \partial_{x}\right)\left(\partial_{a} \cdot \partial_{x}\right)+\frac{1}{2}(a \cdot \partial)^{2} \square_{a}\right] \varphi^{(s)}(a, x),
$$

linearised Einstein-Hilbert (Fierz-Pauli) action for $s=2$.
There is a gauge symmetry with transformation law:
$\delta \varphi^{(s)}(a, x)=(a \cdot \partial) \epsilon^{(s-1)}(a, x), \epsilon^{(s-1)}(x, a)=\frac{1}{(s-1)!} \epsilon_{\mu_{1} \ldots \mu_{s-1}} a^{\mu_{1}} \cdots a^{\mu_{s-1}}$
Constraints: $\square_{a} \epsilon^{(s-1)}(a, x)=0, \square_{a}^{2} \varphi^{(s)}(a, x)=0$.
