

Search for Weakly Interacting Particles with the FASER Experiment Matthias Schott on behalf of the FASER Collaboration

Prof. Dr. Matthias Schott

The general idea

- Huge cross-sections at the LHC
 - N_{inel} ≈ 2.3×10¹⁶ inelastic pp scattering events for an integrated luminosity of 300 fb⁻¹
 - Extremely weakly-coupled and light new particles may be produced in sufficient numbers in the very forward region.
- Such particles may be highly collimated
 - typically produced within $\theta \sim \Lambda_{QCD}/E$
 - implies that ~100 m down-stream, such particles have only spread out ~10 cm in the transverse plane.

- Example I: Dark Photon
 - pp→A'X (here many possible production mechanism)
 - π⁰ -> Α'γ
 - A' travels ~O(100)m,
 - A' → e⁺e⁻, µ⁺µ⁻
- Example II: ALPS
 - dominant production mechanism is Primakoff process γN → aN'X of high energetic photons interacting with the LHC infrastructure
 - FASER would be able to detect ALPs with $m_a \approx MeV$ and $g_{a\gamma\gamma} \approx 10^{-4}$ GeV⁻¹, as those would travel up to 350m and decay then into two photons, which can be detected.

Experimental Site

- 480m from ATLAS collision point (TI12).
- Transfer line connecting SPS and LHC tunnels used for LEP, but now unused
- Limited space
 - The floor of the tunnel needs to be lowered by <50 cm
 - install FASER detector on the beam collision axis

FASER Experiment

ForwArd Search ExpeRiment at the LHC

Low cost

- Small detector (r=10 cm, 5 m long).
- The detectors developed for other experiments will be recycled as much as possible (tracker, calo, DAQ).
- Construction cost: <1MCHF</p>

Quick!

- Aim to construct the detector during LS2 and start data-taking in 2021
- It is big advantage to use detectors that are already used
- Excellent sensitivity!
 - FASER will explore large parameter space of new particles

- Signal: two e⁺e⁻ tracks (or 2y) originating from a new particles
 - 150 fb⁻¹@Run3
- Rocks and LHC shielding eliminates most potential backgrounds.

- High energetic muons and neutrinos are the main backgrounds.
 - ~100Hz of muons going through the tracker
 - 80k muon events with γ or EM/HD shower
 - A few (~100 GeV) CC/NC neutrino events
- Can be reduced to negligible level, assuming charged particle veto with efficiency of 99.99%

Detector Concept

- The detector consists of:
 - Scintillator veto/trigger
 - 1.5m-long decay vol. 0.5-0.6 T magnetic field
 - 2m-long spectrometer with 3 tracking stations in 0.5 T magnetic field
 - EM calorimeter

Prof. Dr. M. Schott (Johannes Gutenberg University, Mainz)

The Spectrometer

- Permanent magnet with ~0.5 T will be used for e⁺e⁻ separation.
- The magnet will be constructed by the CERN magnet group.
- The spectrometer needs to identify two tracks from A'→e⁺e⁻ with >300 µm distance (m_{A'} = 100 MeV).
- Silicon strip detector will be used for the tracker

Permanent magnet block (NdFeB) Magnetic yoke (low carbon steel) Non magnetic internal ring (stainless steel) Non magnetic frame (extruded Cu or Al) Non magnetic shim (stainless steel) Epoxy resin

Tracker

- 80 spare ATLAS SCT barrel modules will be used for FASER tracker.
 - Thanks to ATLAS SCT collaboration!
 - 80 μm pitch with 12.8 cm length.
- FASER tracker consists of 3 stations each with 3 SCT layers
 - One layer consists of 8 SCT modules.
- Quality assurance test was performed.
 - 80 modules were already selected for FASER tracker.

Calorimeter

- FASER EM calorimeter for measuring EM energy, electron/ photon identification, Trigger.
 - 4 spare LHCb outer ECAL modules will be used.
 - Thanks to LHCb for letting us use these modules!
- 66 layers of lead/scintillator (25 radiation length), light out by wavelength shifting fibers.
- ~1% energy reso. for 1TeV electrons.

Scintillator

- Scintillator detectors for
 - Creating a trigger signal.
 - Vetoing charged particles entering the decay volume.
- Require extremely efficient charged particle veto (>99.99%).
 - Important for BG suppression.
 - achieved by 4 layers of scintillators

Muon Flux and other backgrounds

- The muon flux at FASER site was evaluated with FLUKA.
- Due to bending from LHC magnets, muon flux on line-of-sight (LOS) is reduced.
 - µ⁻ tend to be bent to the left and µ⁺ to the right of FASER
 - FASER site is perfect place to escape from muons from IP1!
- Background for ALP searches: high energy neutrino's interacting in the calorimeter to give large EM showers
 - either muon neutrinos leading to hadronic showers with π^0 ,
 - or (more rarely) electron neutrinos interacting to give electrons

Energy threshold	Charged particle flux
[GeV]	$[\rm cm^{-2} \ s^{-1}]$
10	0.40
100	0.20
1000	0.06

Beam Backgrounds and Radiations

Beam background

- The emulsion detector and TimePix beam loss monitor were installed at TI12 in 2018 to measure particle flux.
- The results were consistent with FLUKA expectation.
- Detailed study is ongoing.
- Radiation: FLUKA expectation was confirmed by measurement with BatMon detector:
 - <5 x 10-3 Gy/year</p>
 - <5 x 107 1 MeV neq/year</p>
- Conclusion: FASER does not need radiation hard electronics.

Physics Reach: Dark Photons and Dark Higgs

- FASER has sensitivity to coupling strength of ~10⁻⁵ for dark photon.
 - Assumption: 0 background and 100% efficiency.
 - →FASER, LHCb and Belle2 are complementary and can cover most search region of $m_{A'}$ < 1GeV
 - FASER 2 possible future upgrade with 1m radius and 3000/fb of data.

Physics Reach: Heavy Neutral Leptons and ALPs

- For ALP->γγ decay, magnetic field does not help separate closely spaced decay products
 - maybe pre-shower but challenging to resolve closely spaced (~1mm) high energy photons (>500 GeV)
 - Preliminary studies suggest that events with no tracks and a large EM energy in the calorimeter would be ~background free
 - an ALP signal would be detectable without the need to resolve the 2 photons.

 FASER would be able to detect ALPs with m_a≈MeV and g_{aγγ}≈10⁻⁴ GeV⁻¹, as those would travel up to 350m and decay then into two photons, which can be detected.

Schedule towards data-taking

- Documentation and approval
 - Letter Of Intent (LOI) was submitted to LHCC in July 2018 (arXiv:1811.10243).
 - Technical Proposal (TP) was submitted to LHCC in November 2018 (arXiv:1812:09139)
 - The experiment was approved by CERN at Research Board on March 5th 2019.
- Funding for detector construction/ operation was secured from <u>Simons</u> <u>Foundation</u> and <u>Heising-Simons</u> <u>Foundations</u>.
- Timeline
 - Construction/Comm. is planned during LS2.
 - Detector installation is foreseen in May 2020.
 - Data-taking will start from 2021, synchronizing with LHC Run3

synchronizing with LHC Run3. Prof. Dr. M. Schott (Johannes Gutenberg University, Mainz)

UNIVERSITÄT MAINZ

JOHANNES GUTENBERG

Summary

- FASER will search for new light particles coming from ATLAS pp collision point (IP1)
 - can explore uncovered parameter space, and is complementary with searches by LHCb and Belle2.
- The detector will be installed at 480 m away from IP1 where SPS and LHC rings are connected and is based on spare LHC experiment detector components
- Workintensive years ahead to get everything ready in time

Prof. Dr. Matthias Schott
