

Chargino search

Disappearing track  
analysis

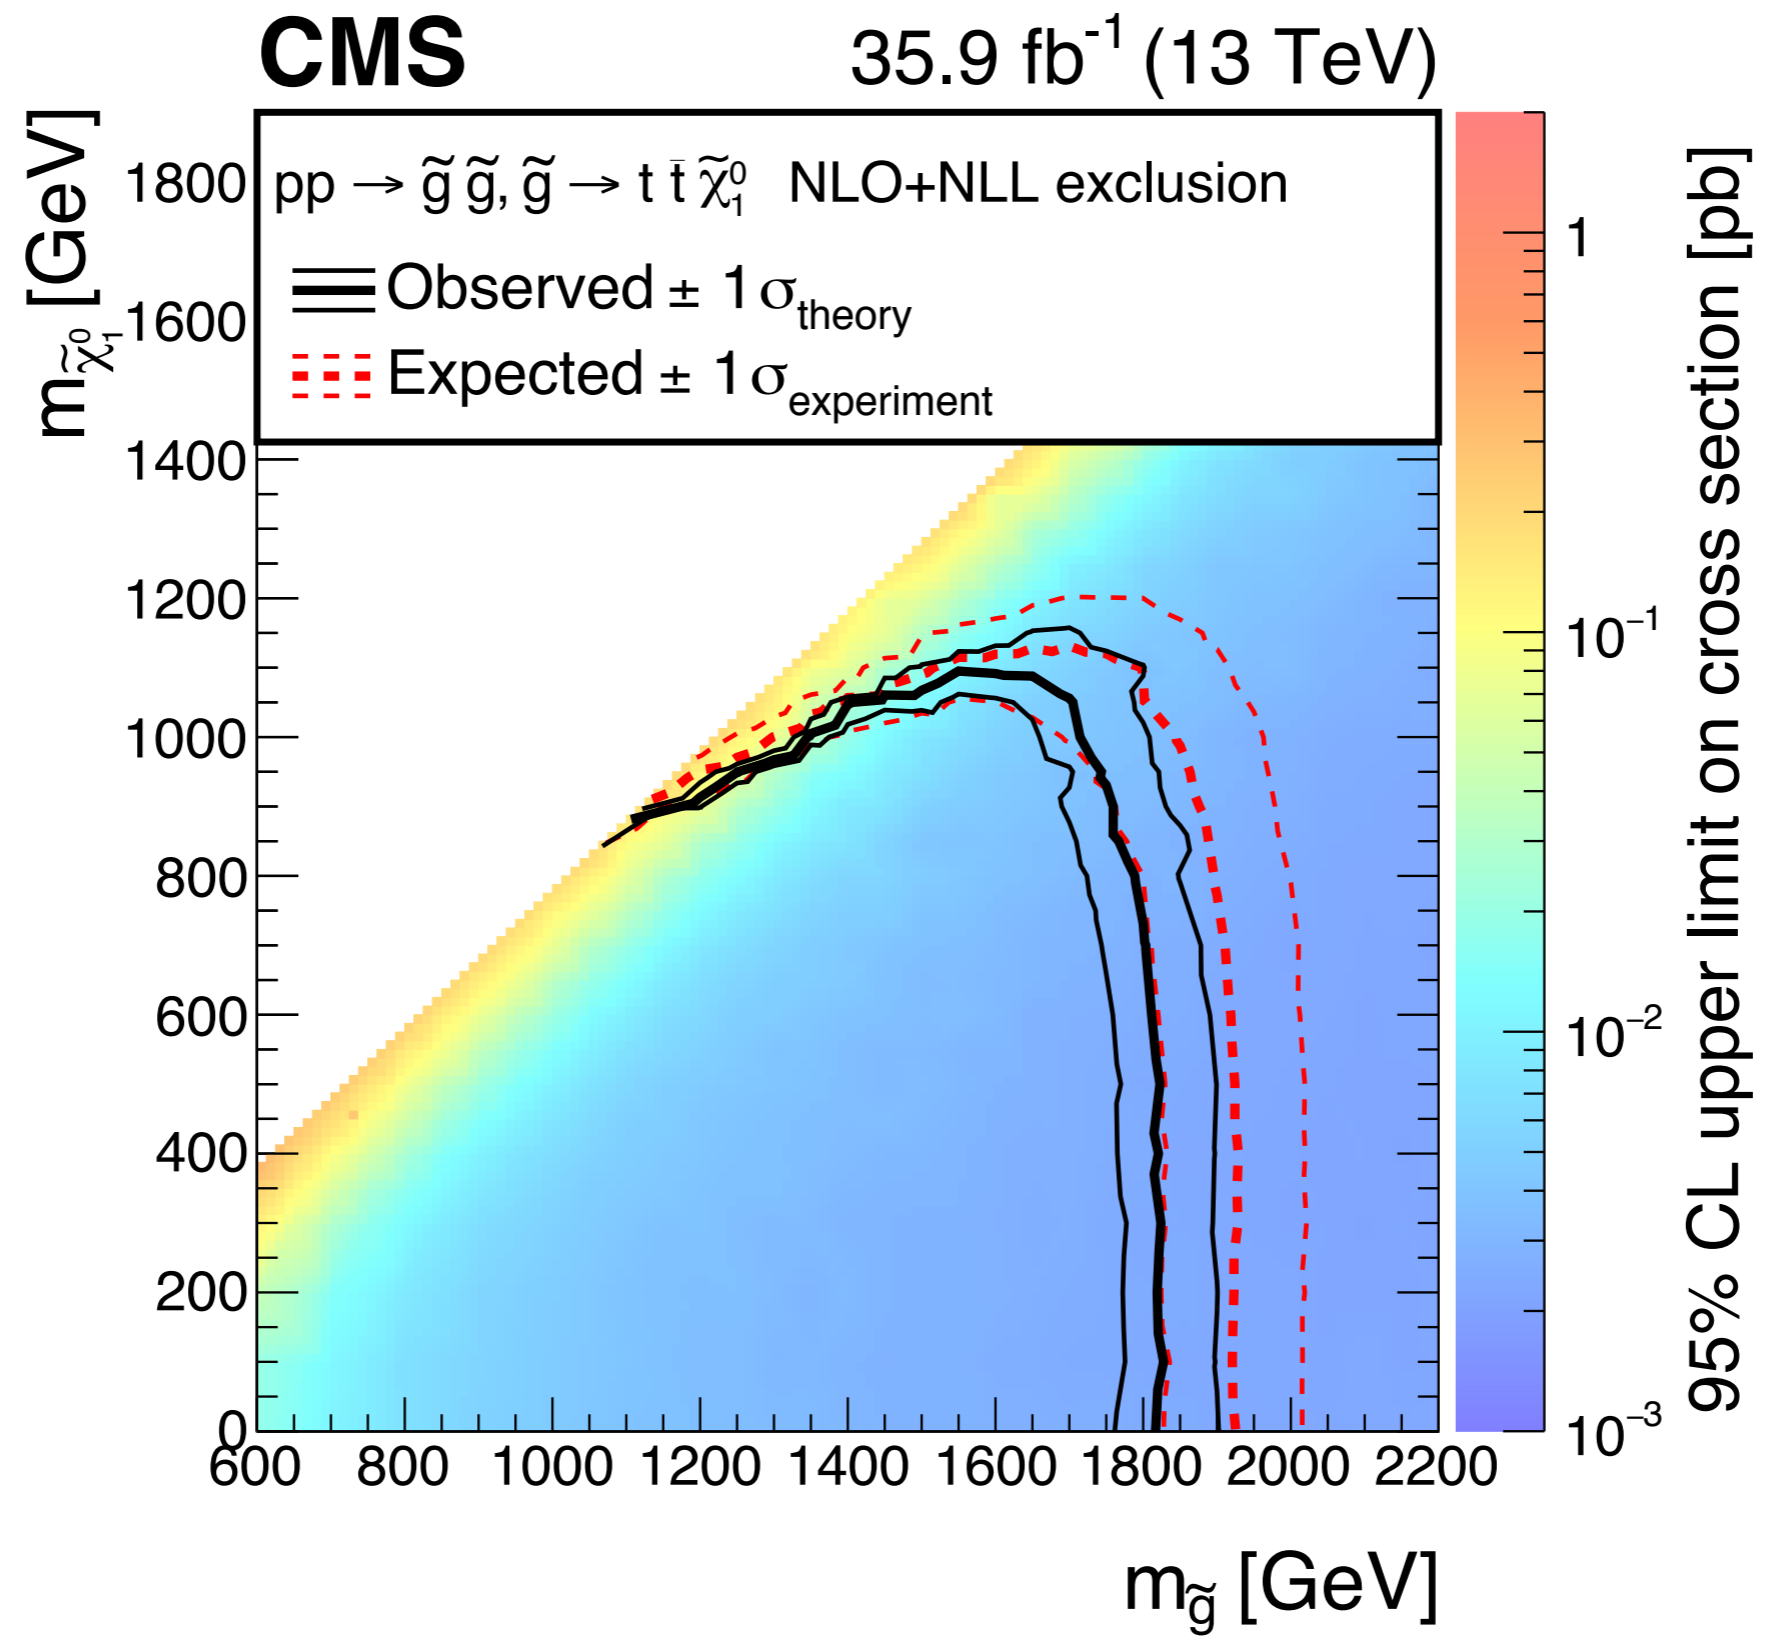

# T1tttt: Signal model

## Final State

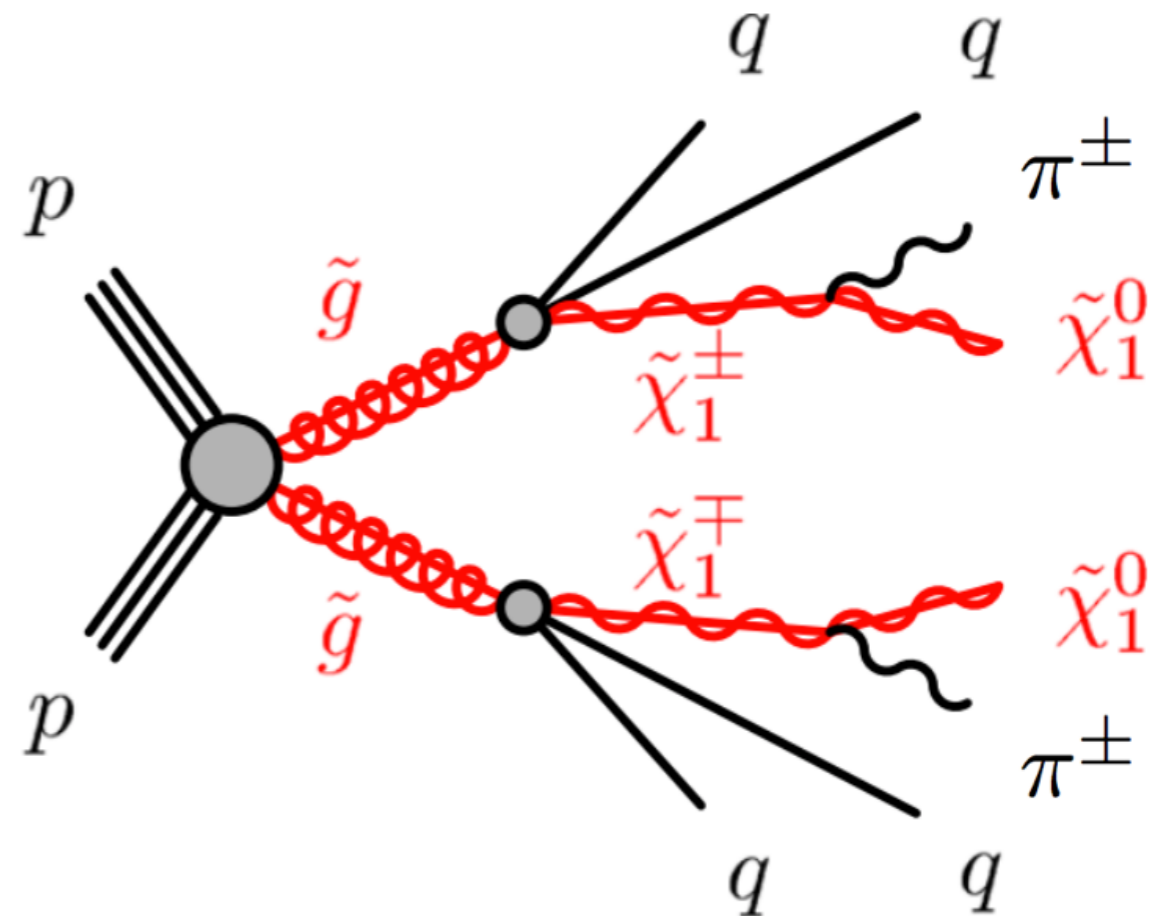

- One **isolated lepton**
- High **jet multiplicity**
- Multiple  $b$ -jets
- High **MET**

# Exclusion limits

# Chargino production

- Direct production via electroweak interactions.
- Indirect production; emitted in cascade decay of coloured particles.
- Multiple energetic jets
- Large missing transverse energy from Neutralinos
- At least one disappearing track

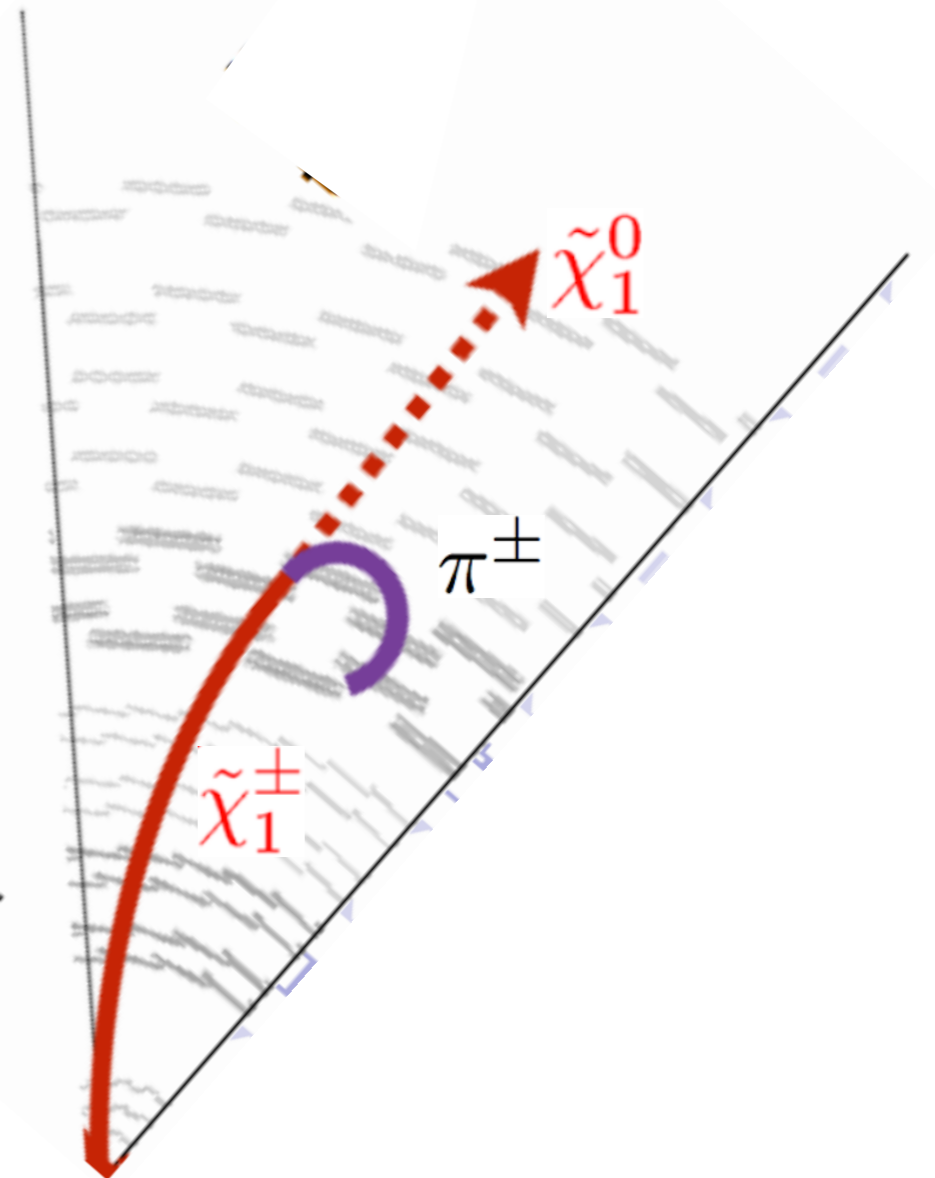

T1qqqq: Signal Model

# Signature of the chargino

- Chargino decays to neutralino and a W boson;
- If chargino-neutralino mass splitting is of the order of pion mass, charginos are long lived;
- W boson is assumed to go to a pion with transverse momentum given by:

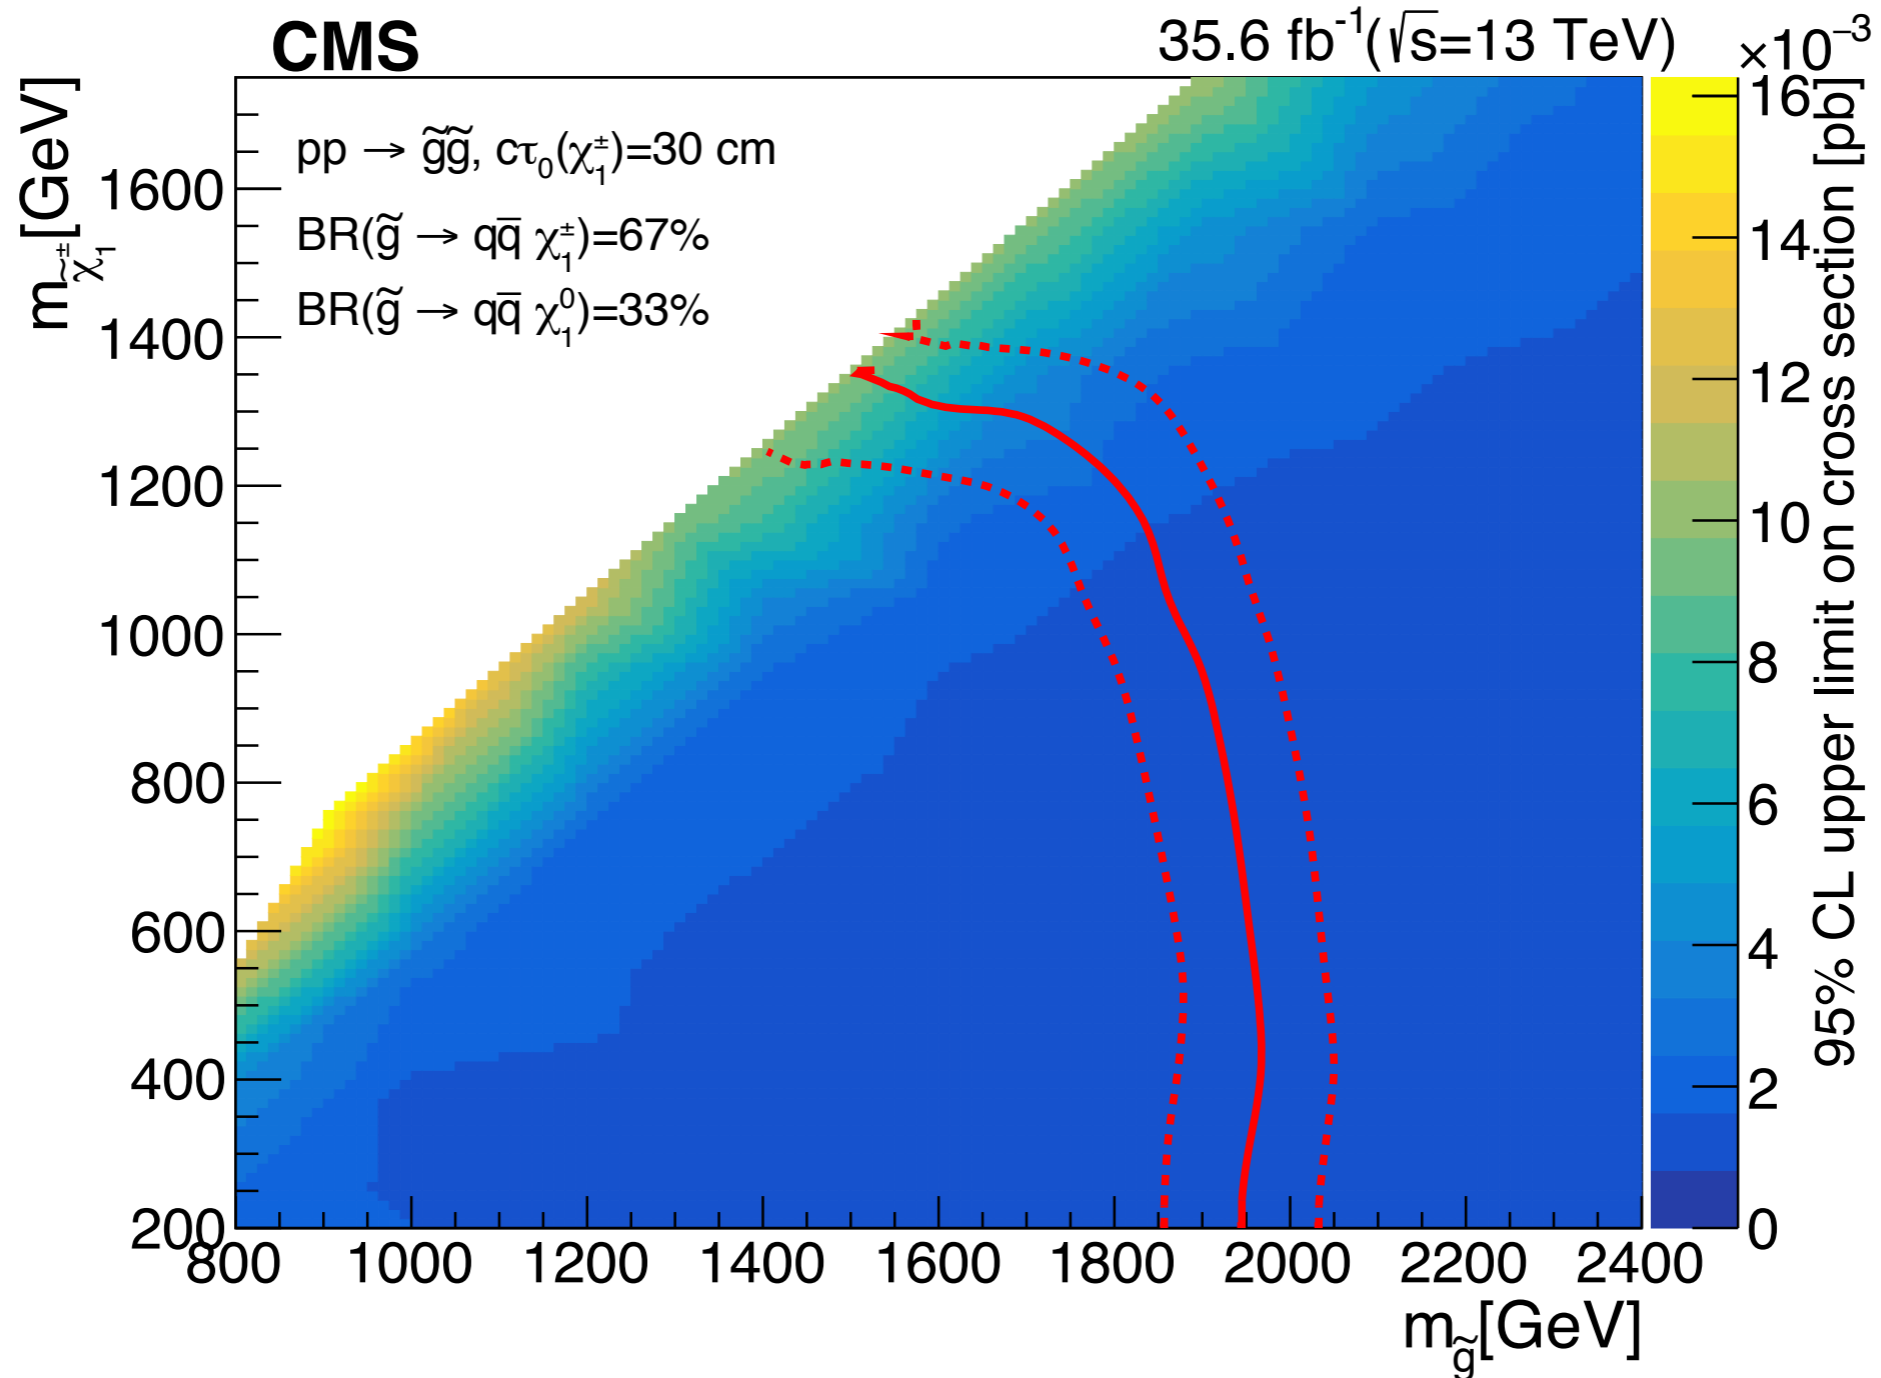

$$p_{\pi} = \sqrt{(m_{\tilde{\chi}_1^{\pm}} - m_{\tilde{\chi}_1^0})^2 - m_{\pi}^2}$$

- The chargino track appears to disappear as pion is not reconstructed.

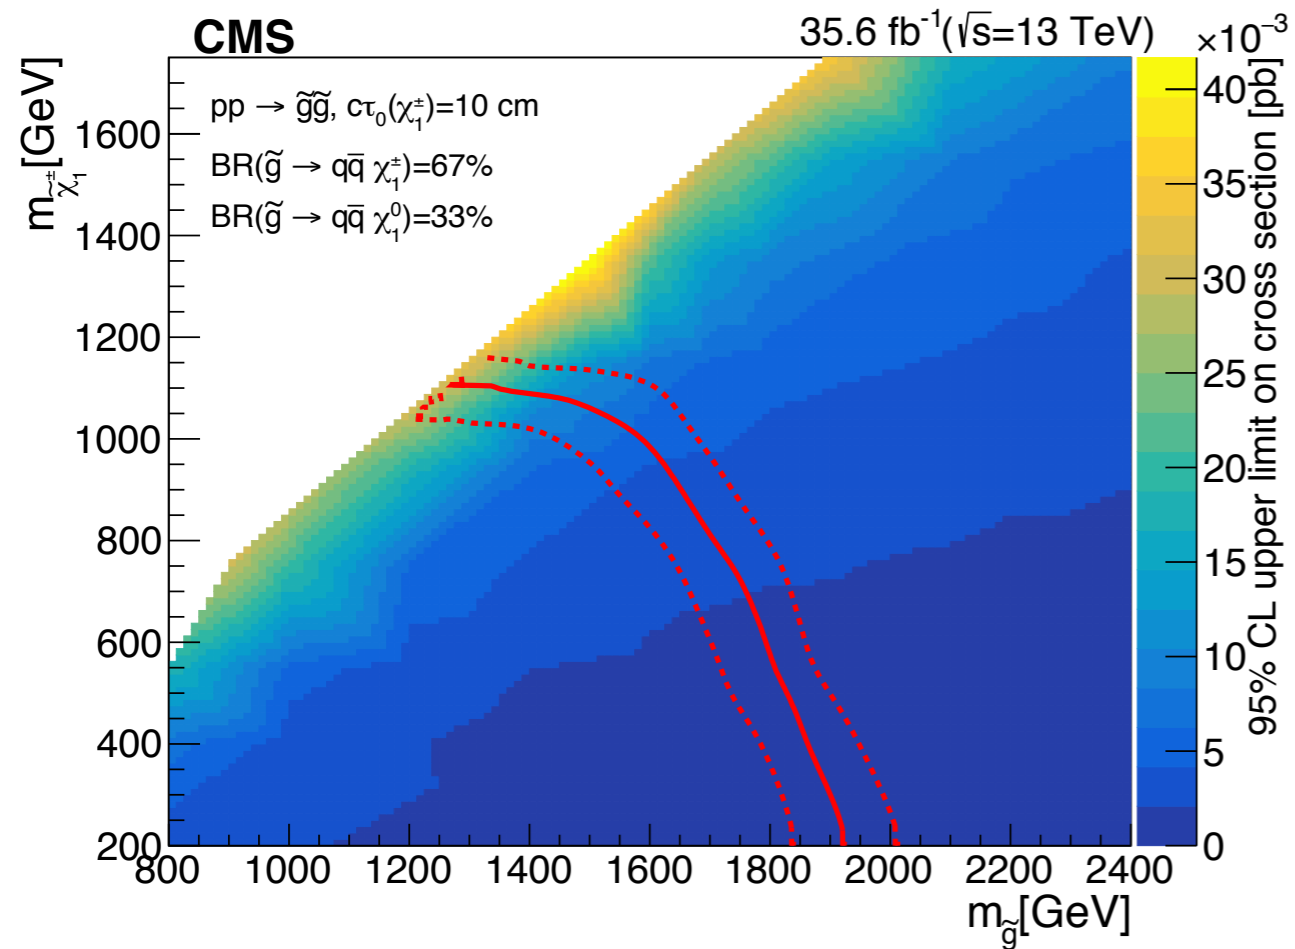

# Expected Exclusion limits

**Proper lifetime = 1 ns**

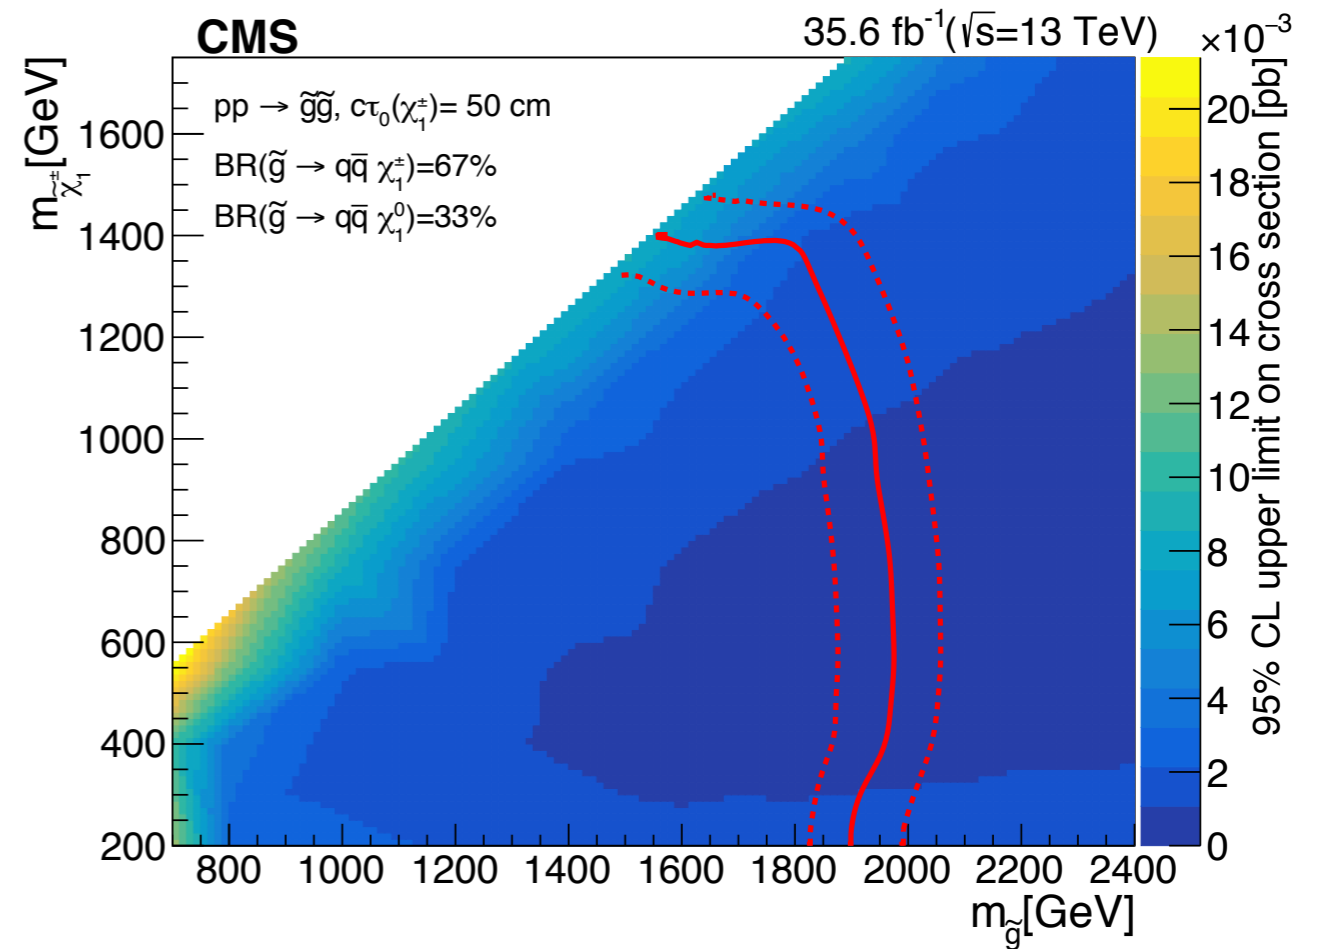

# Expected Exclusion limits

Proper lifetime = .33 ns

Proper lifetime = 1.67 ns

**Thanks!**

# Disappearing track selection

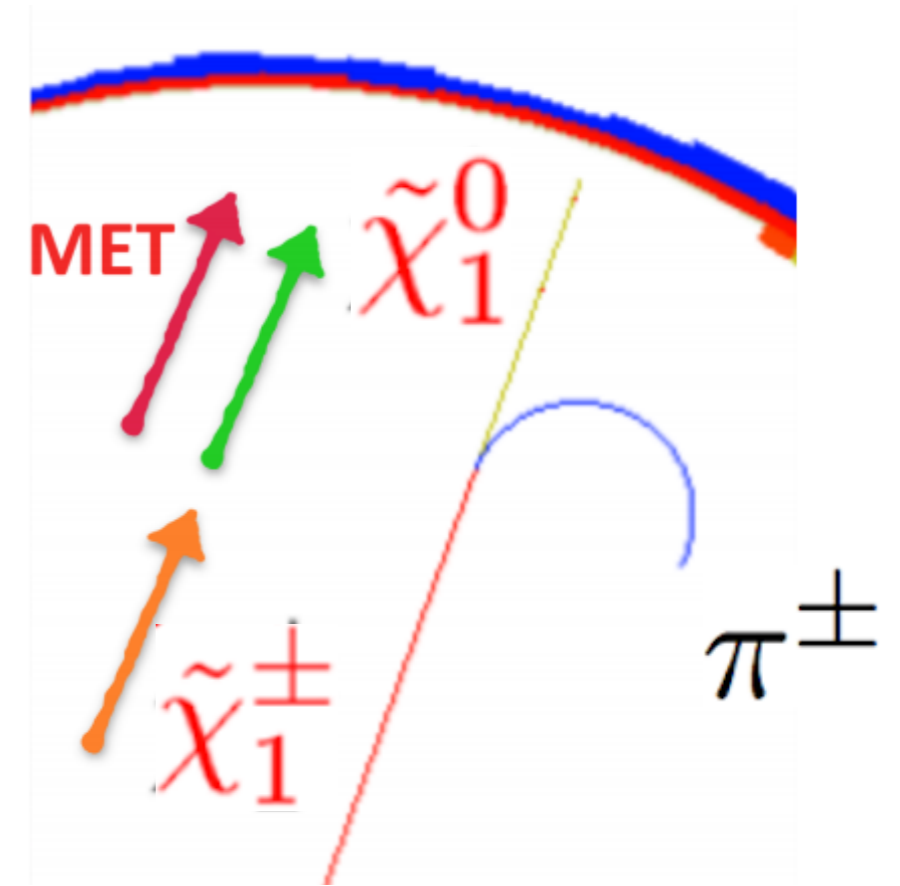

- passes baseline track selection
- $d_{xy} < 0.01$  cm and  $d_z < 0.02$  cm
- absolute (relative) isolation from charged PF candidates  $< 10$  GeV (0.01)
- absolute (relative) isolation from neutral PF candidates  $< 10$  GeV (0.01)
- energy deposited in ECAL  $< 10$  GeV in cone of  $dR < 0.5$
- relative isolation of the track  $< 0.2$
- missing inner hits = 0
- $p_T^{error}/p_T^2 < 0.2$  for short ,  $< 0.05$  for medium and  $< 0.02$  for long tracks
- missing outer hits  $\geq 2$  for medium and long tracks

# Search variables

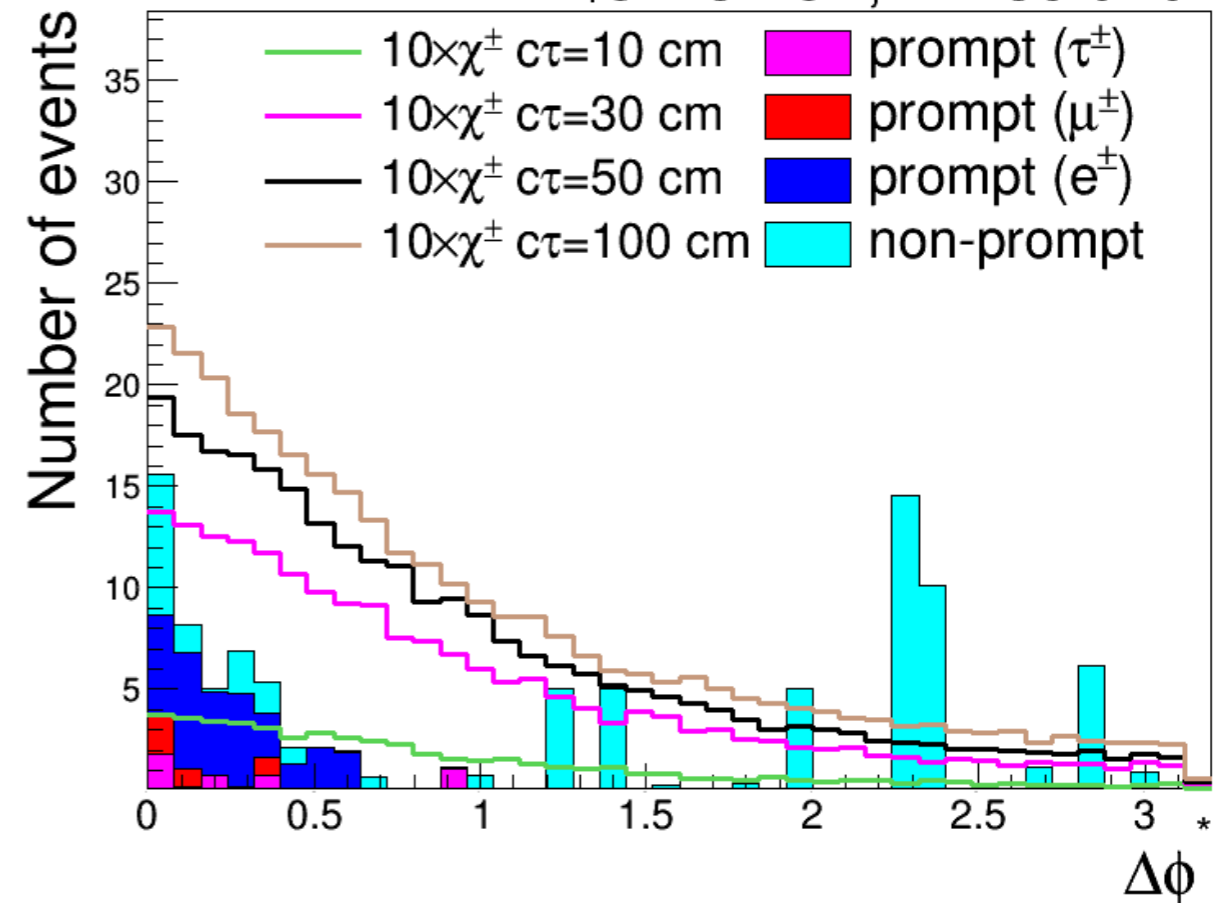

- Chargino decays to a soft pion and a neutralino;
- To a very good approximation the sum of the disappearing tracks is same a missing transverse energy in an event;

$$\Delta\Phi^* = \Delta\phi(\vec{E}_T^{\text{miss}}, \sum_1^n \tilde{P}_T^n)$$

- Fake background is reduced by 20% for delta phi < 2.5 selection.
- Facilitates background prediction.

$\sqrt{s}=13 \text{ TeV}, L = 35.9 \text{ fb}^{-1}$

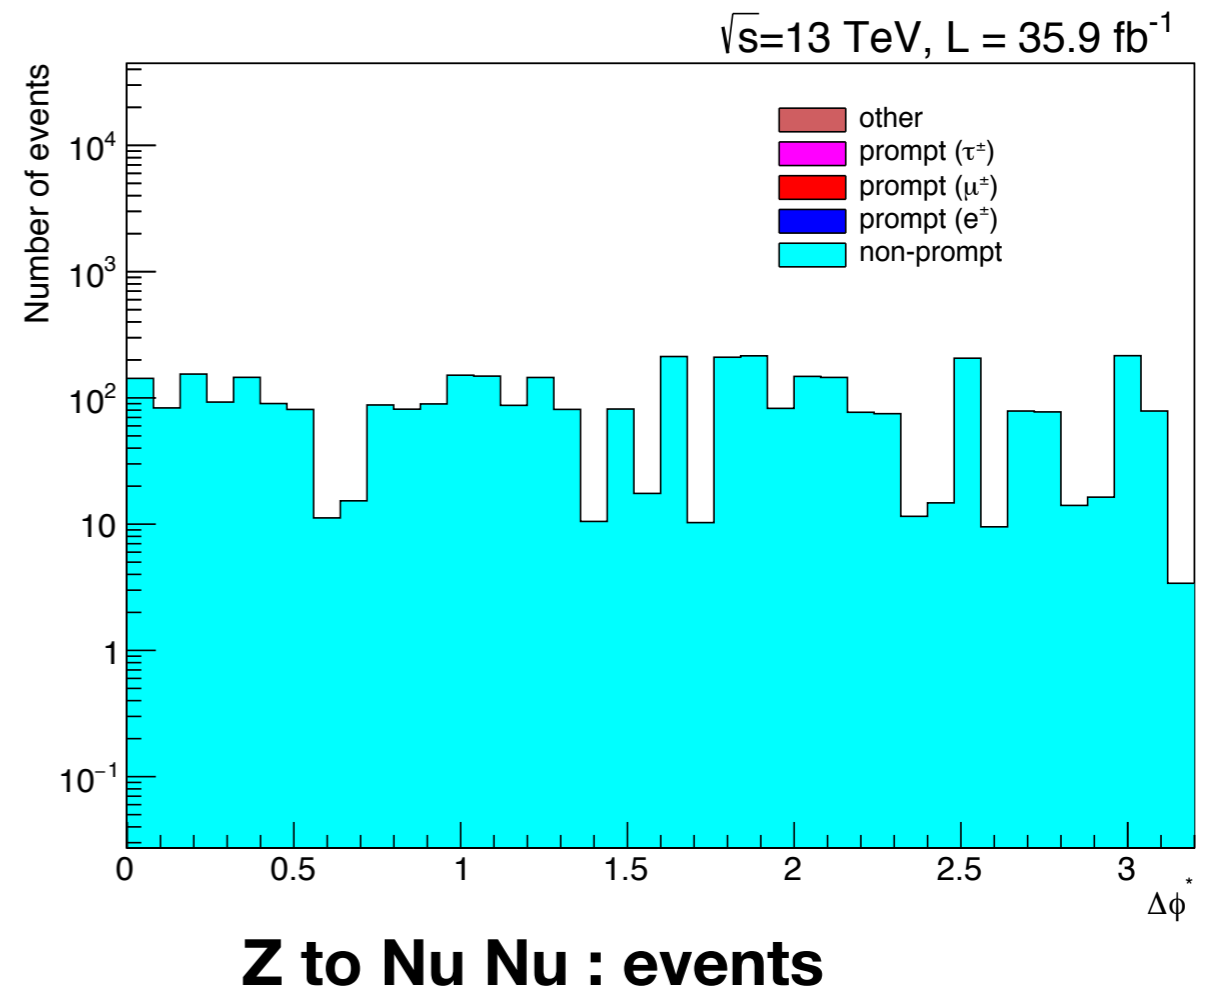

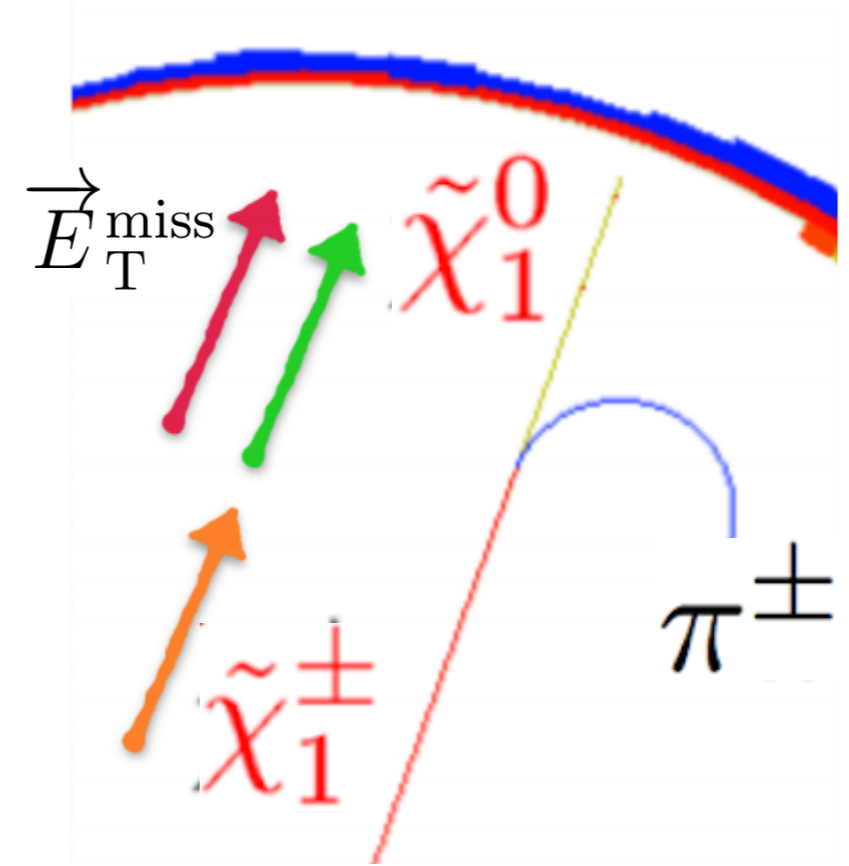

# Search variables

- Chargino decays to a soft pion and a neutralino;
- To a very good approximation the sum of the disappearing tracks is same a missing transverse energy in an event;

$$\Delta\Phi^* = \Delta\phi(\vec{E}_T^{\text{miss}}, \sum_1^n \tilde{P}_T^n)$$

- Fake background is reduced by 20% for delta phi < 2.5 selection.
- Facilitates background prediction.

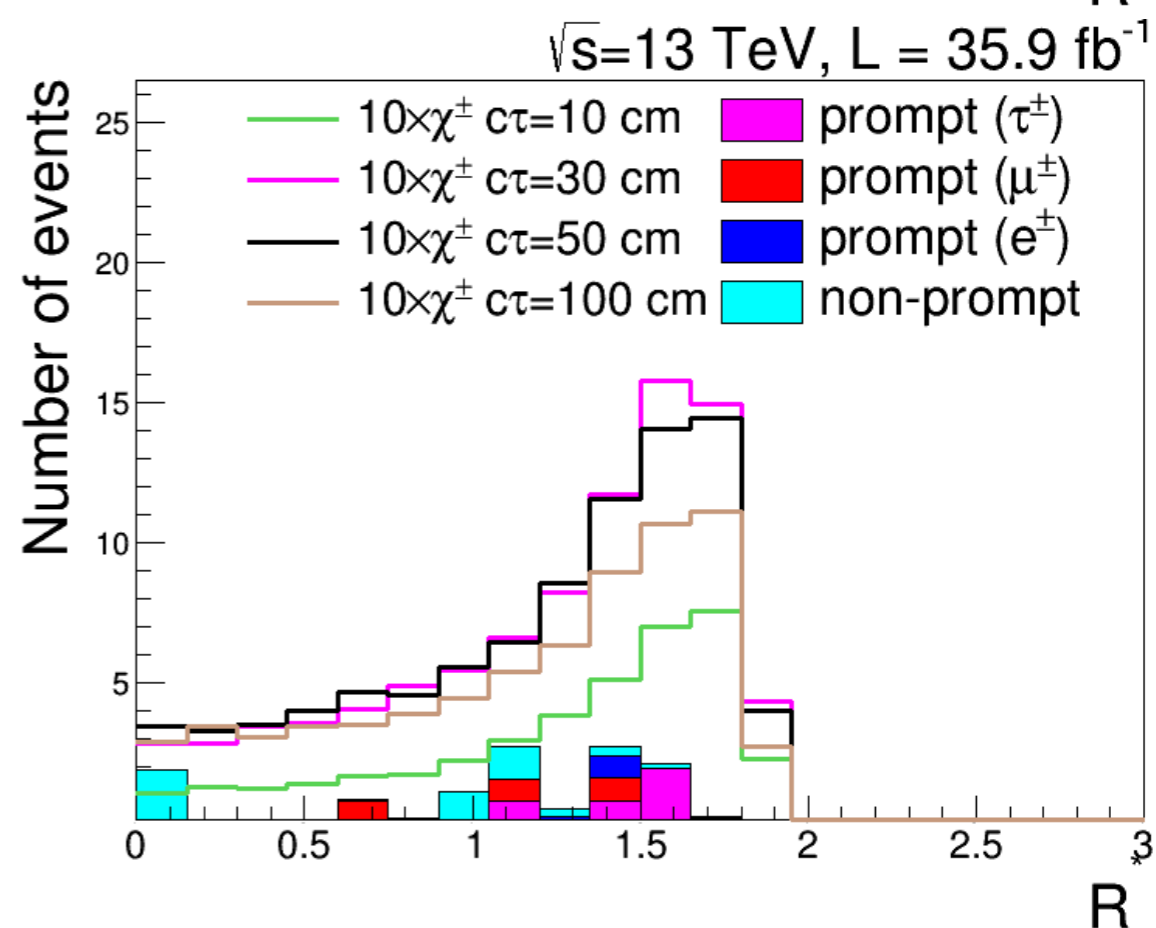

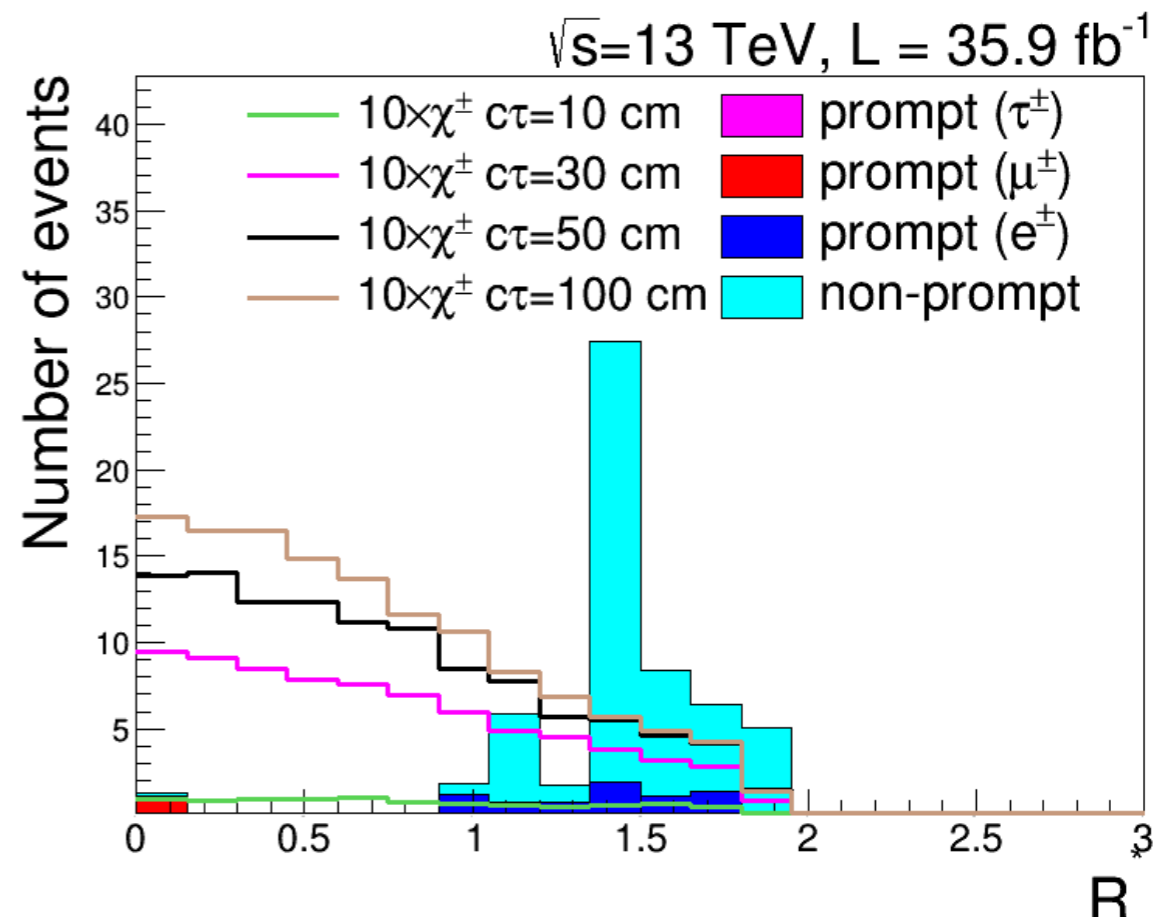

# Search variables

- Variable to compare the magnitude of MET and the sum of disappearing tracks;

$$\mathcal{R}^* = 2 \cdot \frac{||\vec{E}_T^{\text{miss}}| - |\sum_1^n \tilde{P}_T^n||}{|\vec{E}_T^{\text{miss}}| + |\sum_1^n \tilde{P}_T^n|}$$

- Distribution for long and medium tracks; falling from zero to two (top);
- Distribution for short tracks; increasing from zero to two(bottom);

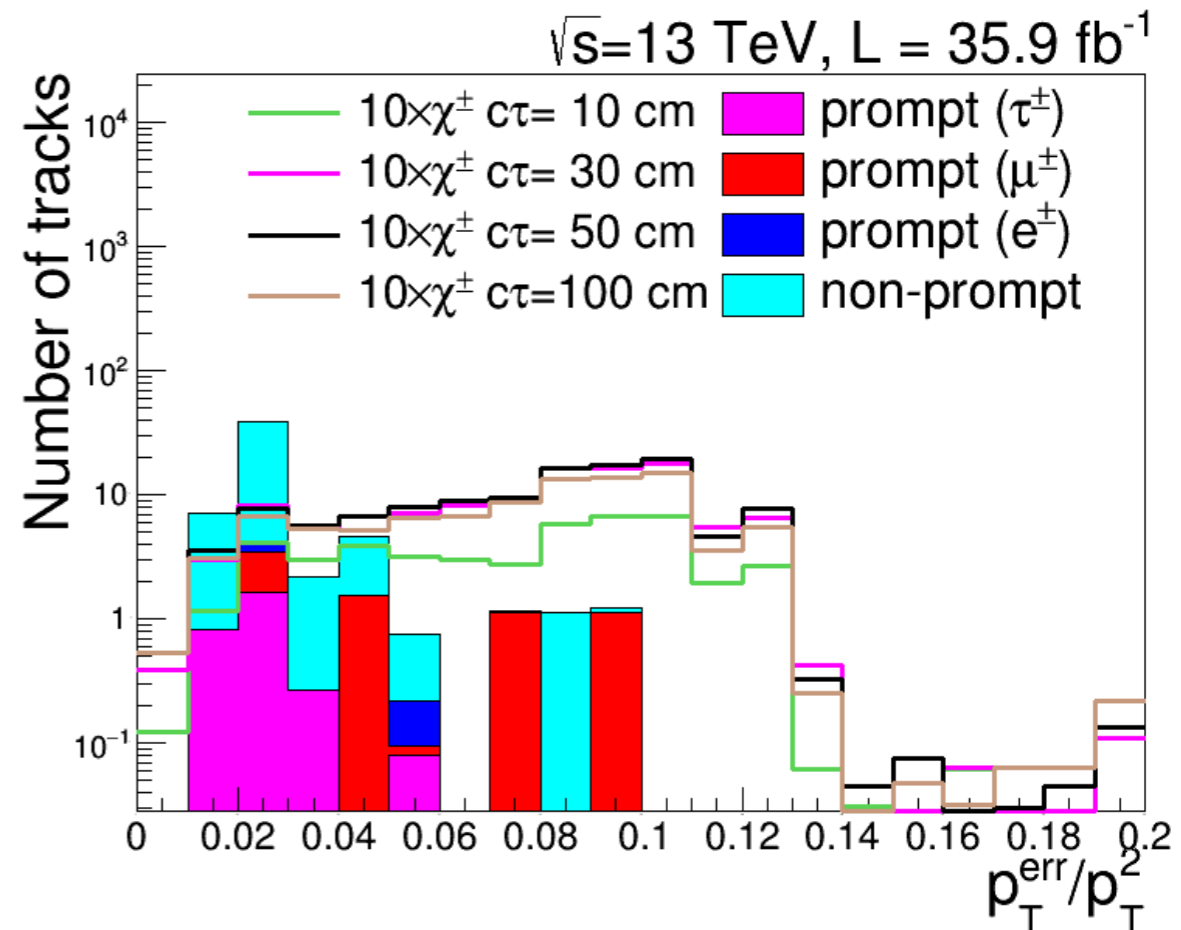

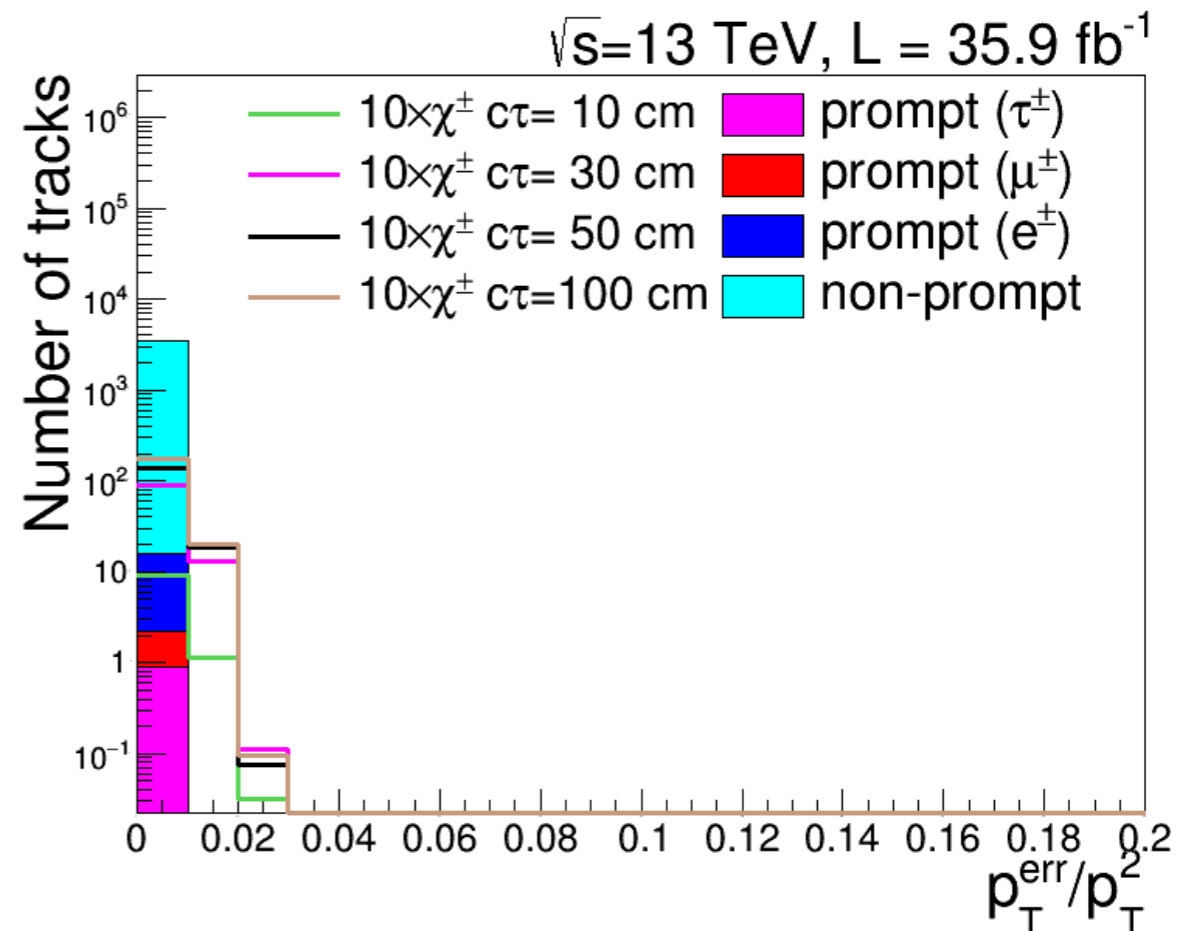

# Search variables

- Variable to compare the magnitude of MET and the sum of disappearing tracks;

$$\mathcal{R}^* = 2 \cdot \frac{||\vec{E}_T^{\text{miss}}| - |\sum_1^n \tilde{P}_T^n||}{|\vec{E}_T^{\text{miss}}| + |\sum_1^n \tilde{P}_T^n|}$$

- Distribution for long and medium tracks; have good Pt resolution (top);
- Distribution for short tracks; have bad Pt resolution (bottom);
- Used for binning the search region.

# Search region

- number of disappearing tracks  $\geq 1$
- $H_T > 250$  GeV,  $H_T = \sum p_T^{jets}$
- $MHT > 250$  GeV,  $MHT = -\sum \vec{p}_T^{jets}$
- number of jets  $\geq 1$
- number of veto leptons = 0
- $\Delta\Phi^* < 2.5$ ,  $\Delta\Phi^* = \Delta\phi(\vec{E}_T^{\text{miss}}, \sum \tilde{p}_T^{\text{tracks}})$

# Search regions

- Search is binned into 8 search regions;
- Binning in **R**, makes the search sensitive to the different chargino **lifetimes**;
- Binning in HT and MHT makes the search sensitive to different mass parameters of the signal model.

$\mathcal{R}^*$	MHT [GeV]	$H_T$ [GeV]
[0,1]	[250,400]	[250, 600]
		(600, $\infty$ ]
	(400, $\infty$ ]	[250, 600]
		(600, $\infty$ ]
(1,2]	[250,400]	[250, 600]
		(600, $\infty$ ]
	(400, $\infty$ ]	[250, 600]
		(600, $\infty$ ]

Eight search regions

# Leptonic background estimation

- Estimated by measuring a transfer factor kappa as a function of transverse momentum and pseudo rapidity as:

$$\kappa = \frac{\mathcal{P}(\text{disappearing track} || \text{true lepton})}{\mathcal{P}(\text{lepton} || \text{true lepton})}$$

- Control region ; events with exactly one veto lepton

$$(\text{Signal Region})_{\text{events}} = \kappa \times (\text{Control Region})_{\text{events}}$$

- Kappa is measured by tag-and-probe method in data.
- Smearing of probe leptons using smearing templates.

# Kappa calculation

- Calculation by tag-and-probe:

$$\kappa = \frac{\text{Number of probes identified as disappearing track}}{\text{number of probes identified as an lepton}}$$

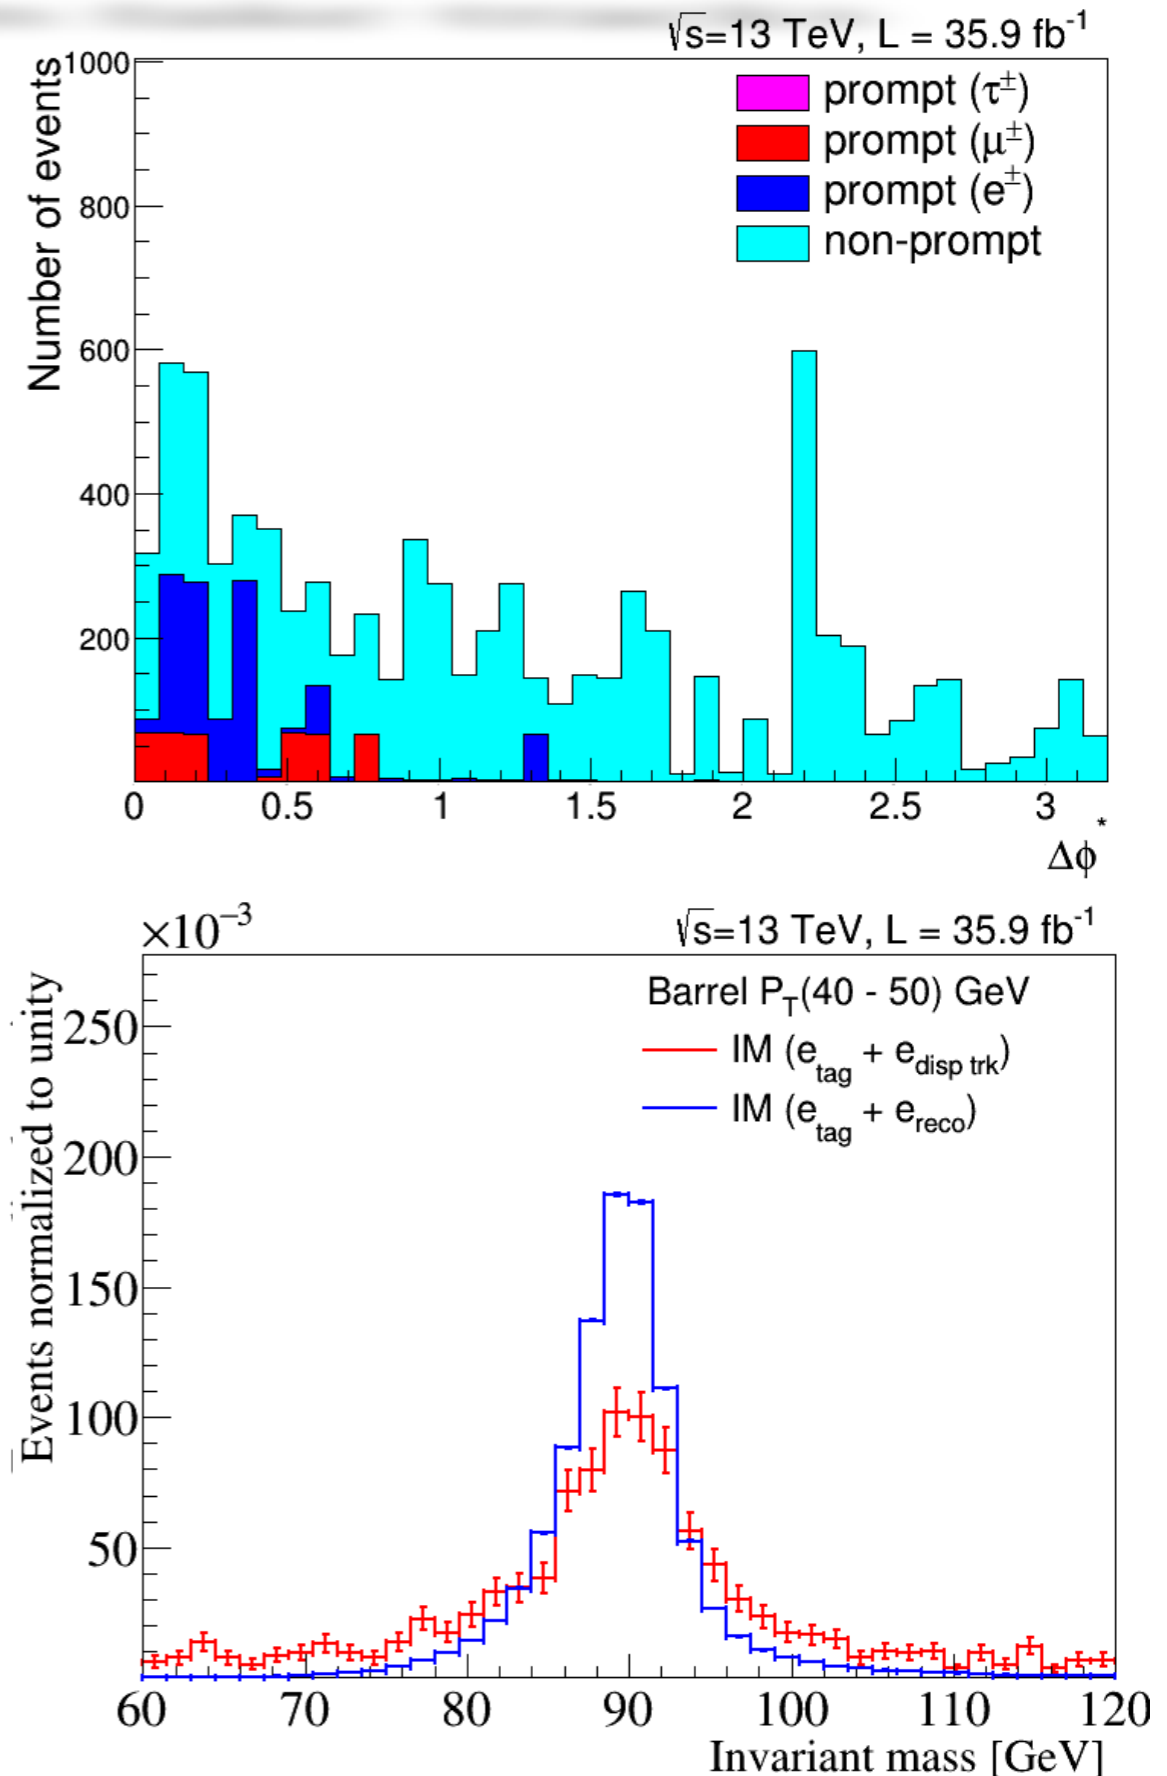

- In simulated samples; using generator information;
  - Generator level lepton is treated as true lepton;
  - Used to prove the independence of kappa from event dynamics.

# Contamination from fake tracks

- Delta Phi distribution of probes; disappearing tracks in events with on tag lepton and no b-jets (top);
- Remove fake contamination using:

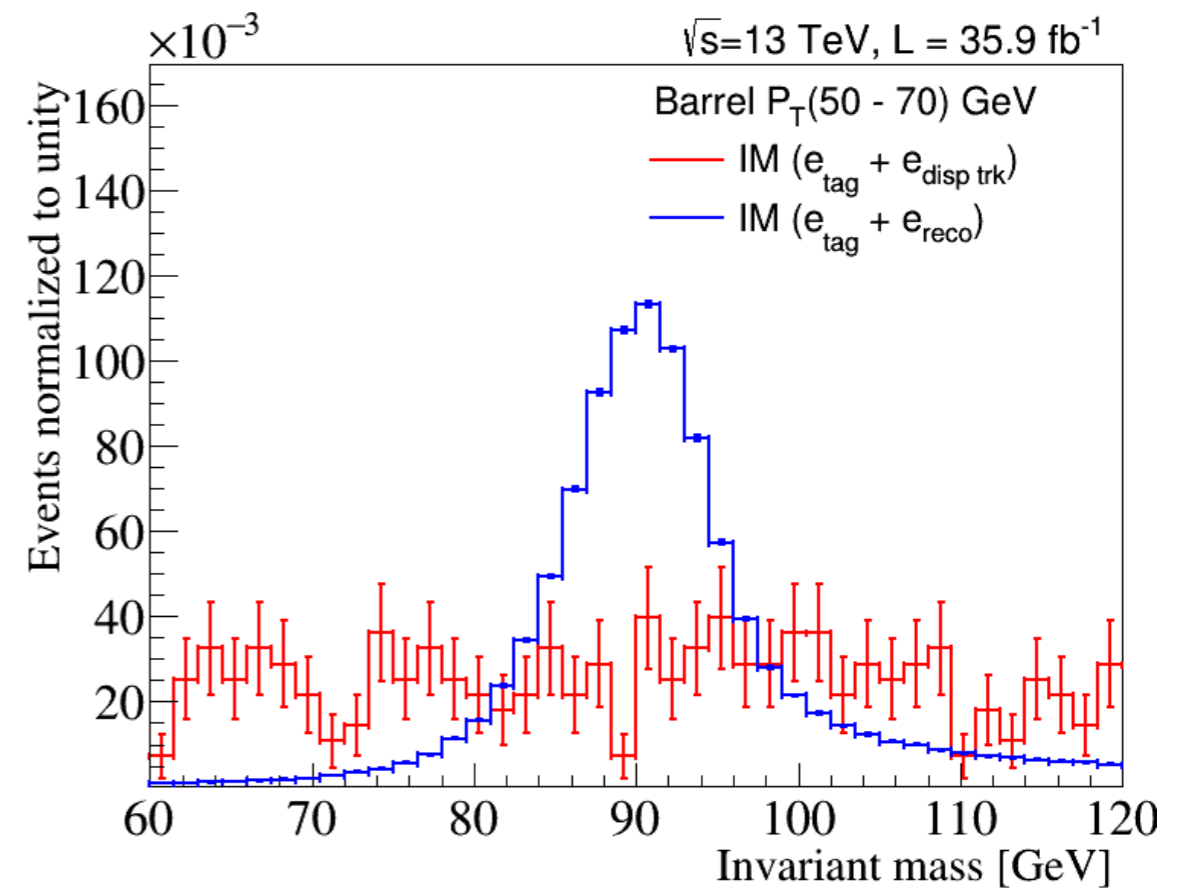

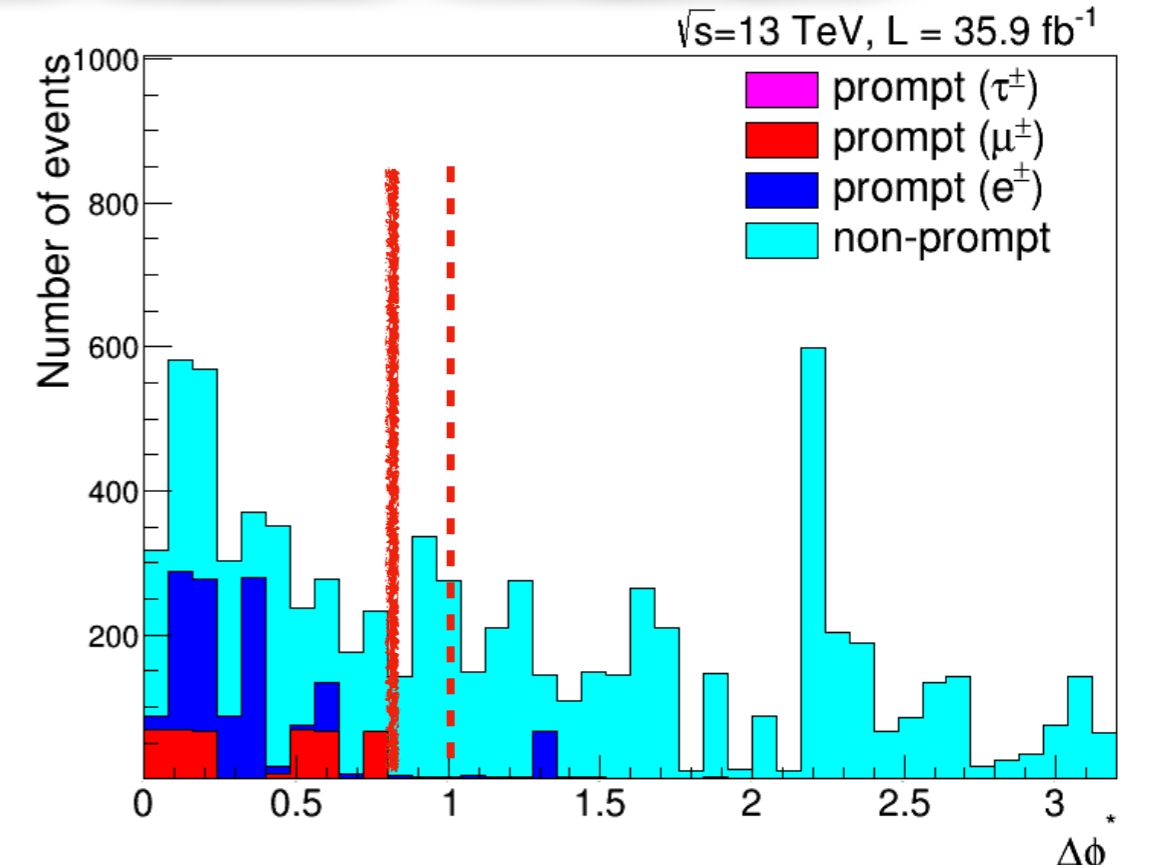

$$\Delta\Phi^* = \Delta\phi(\vec{E}_T^{\text{miss}}, \sum_1^n \tilde{P}_T^n)$$

- Invariant mass distribution in data for tag electron with reco electron and disappearing tracks with no selection on Delta Phi (bottom).

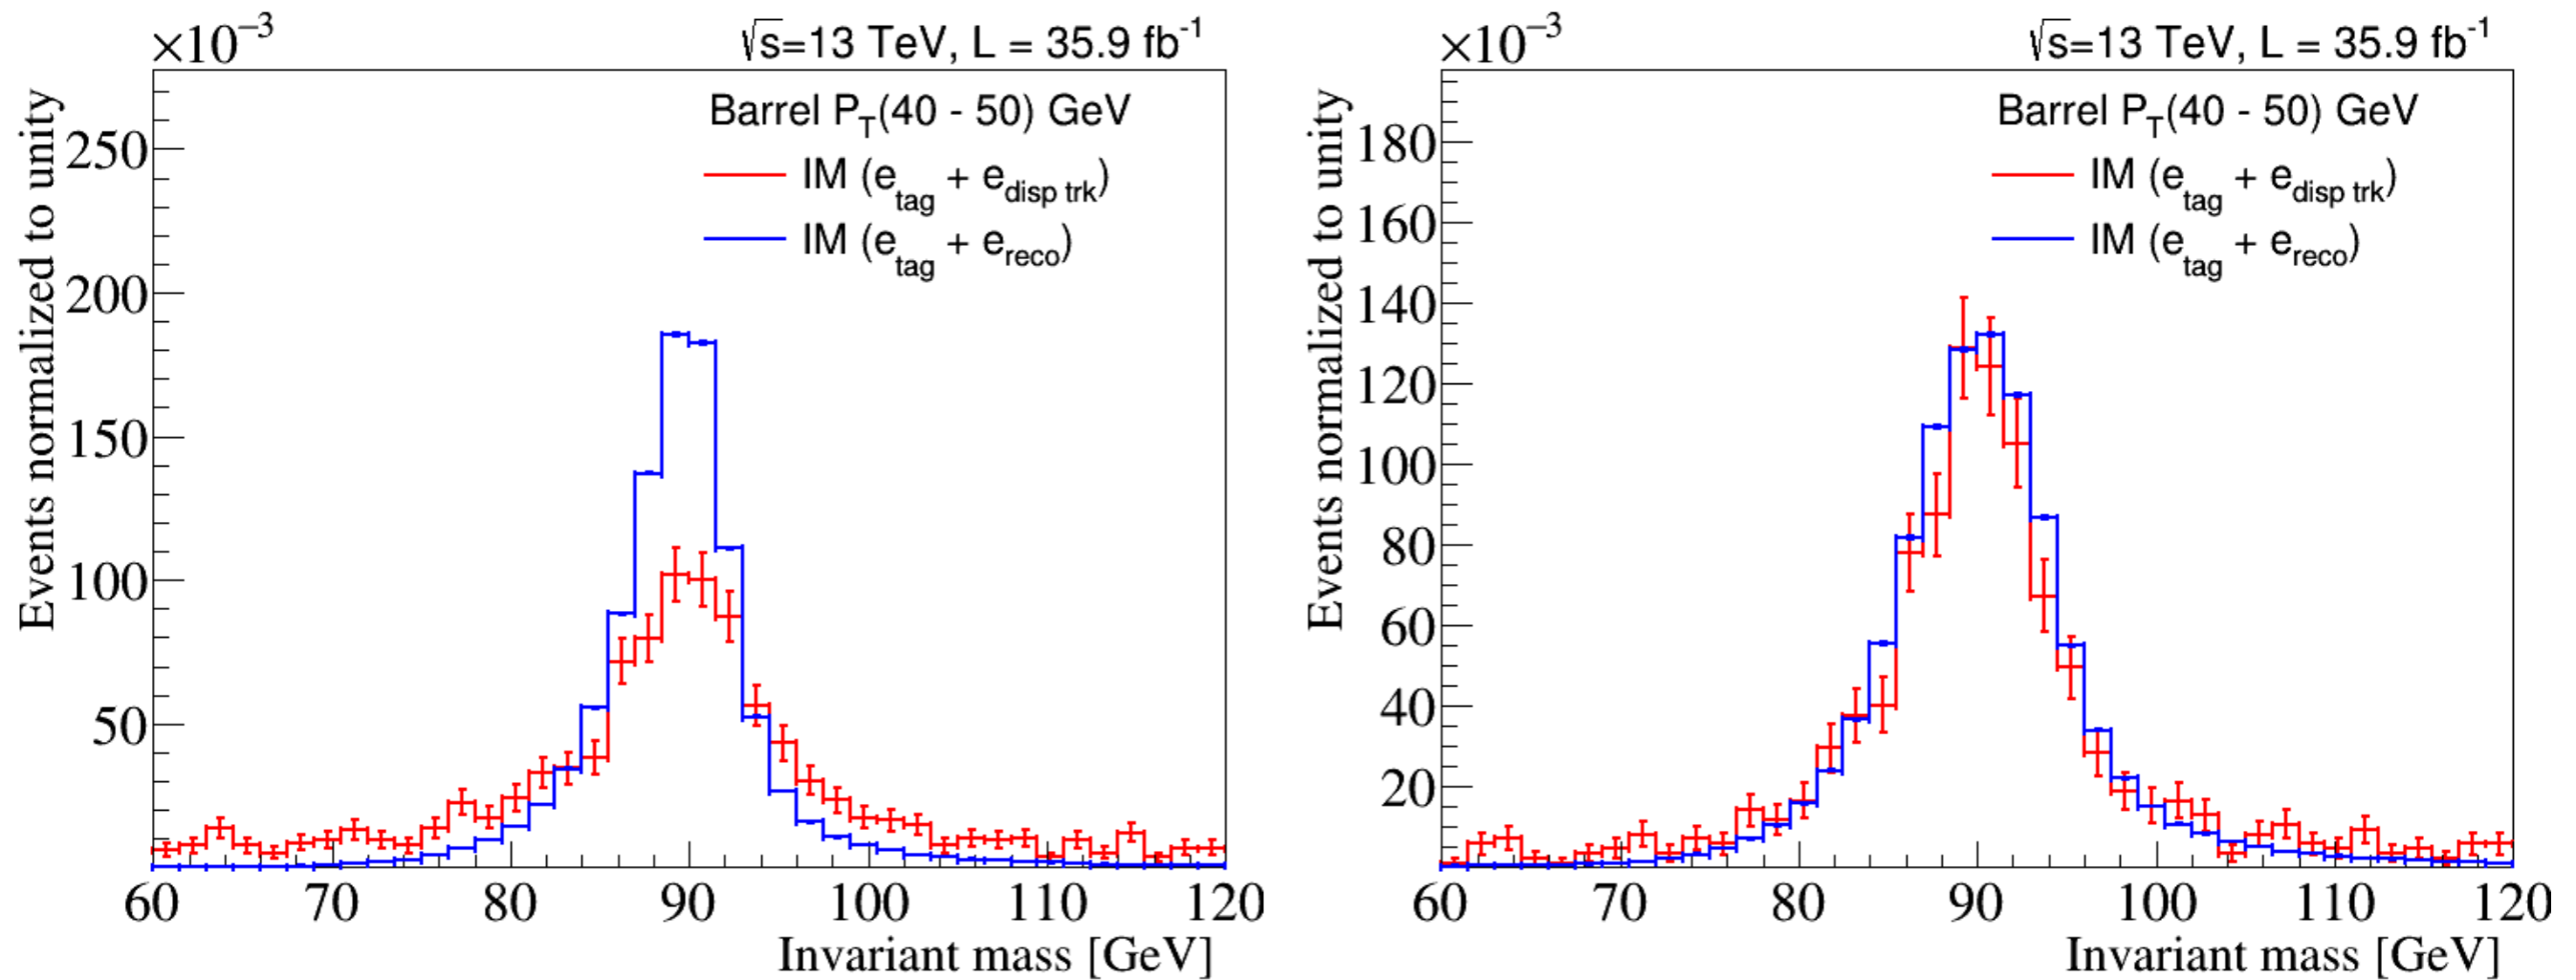

# Contamination from fake tracks

- Delta Phi distribution of probes; disappearing tracks in events with on tag lepton and no b-jets (top);
- Veto disappearing tracks with:
  - $\Delta\Phi^* < 0.8$ ;  $p_T^{\text{error}}/p_T^2 < 0.05$
  - $\Delta\Phi^* < 1.0$ ;  $p_T^{\text{error}}/p_T^2 \geq 0.05$
- Invariant mass distribution for tag electron with reco electron and disappearing tracks with inverted selection on Delta Phi (bottom).

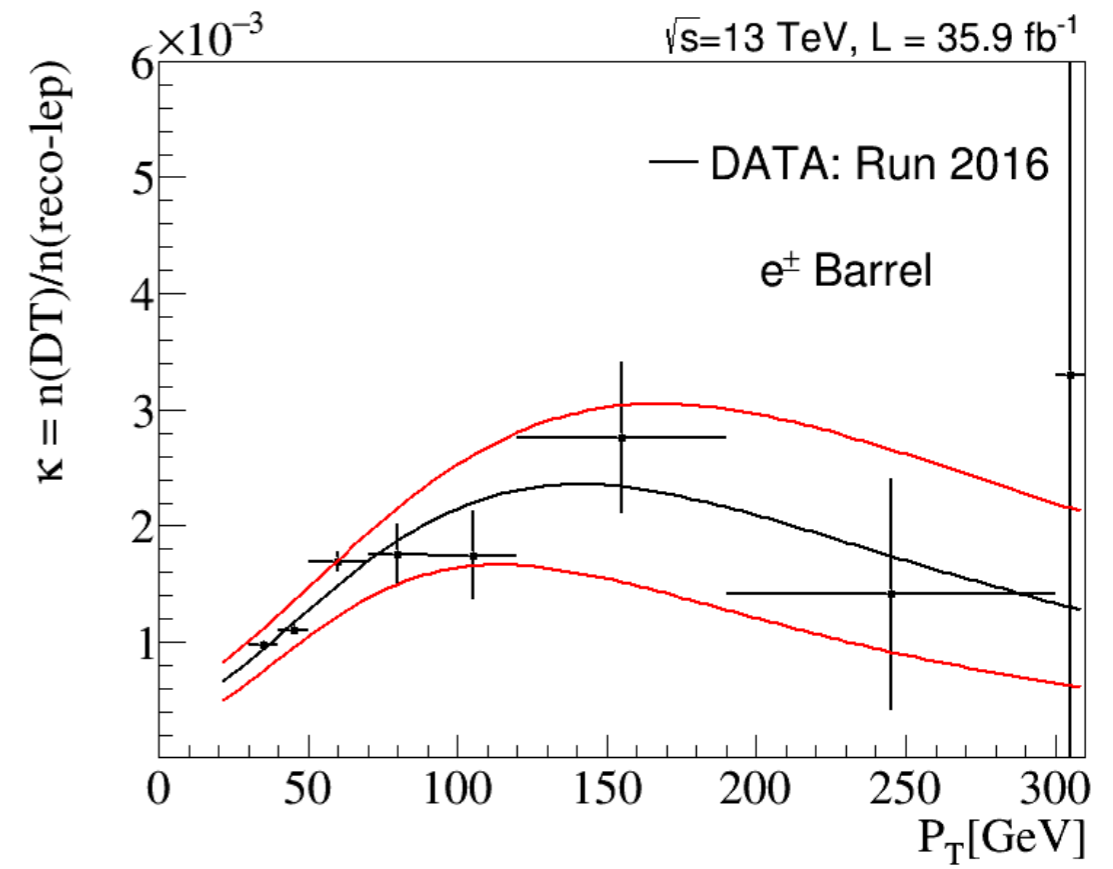

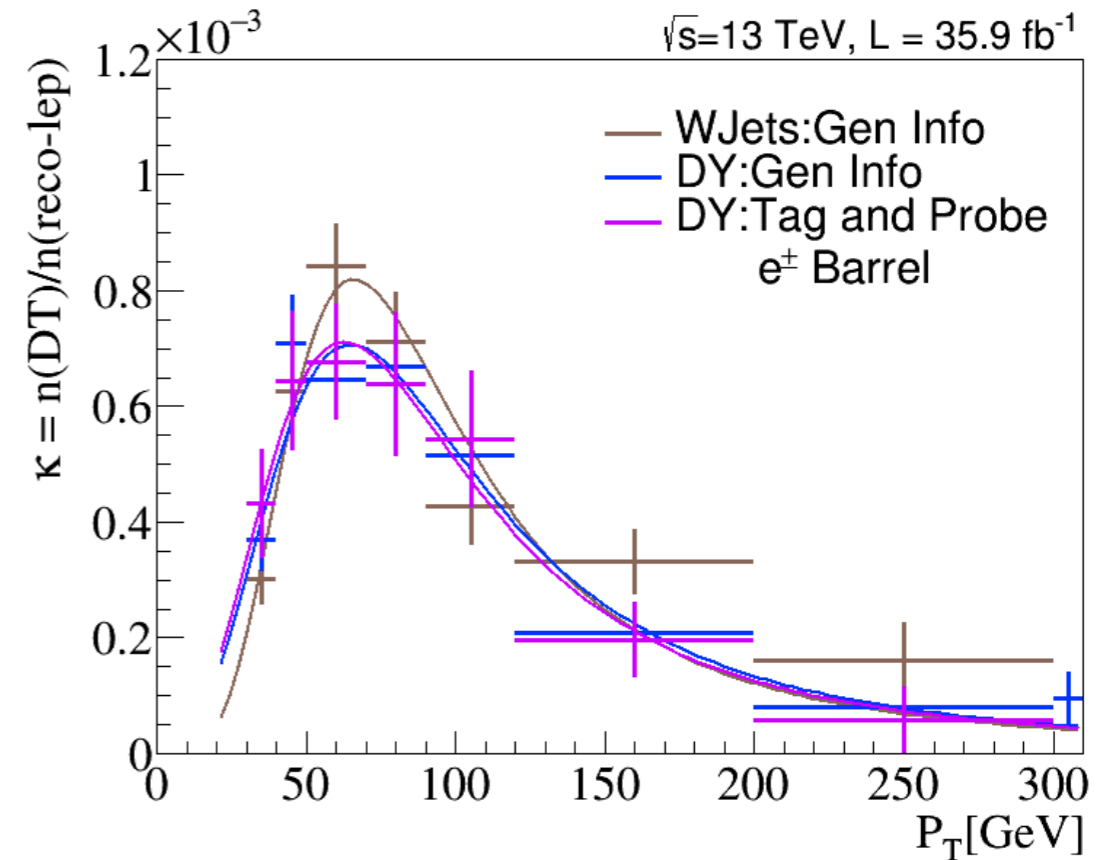

# Effect of corrections

Comparable distributions give accurate kappa values

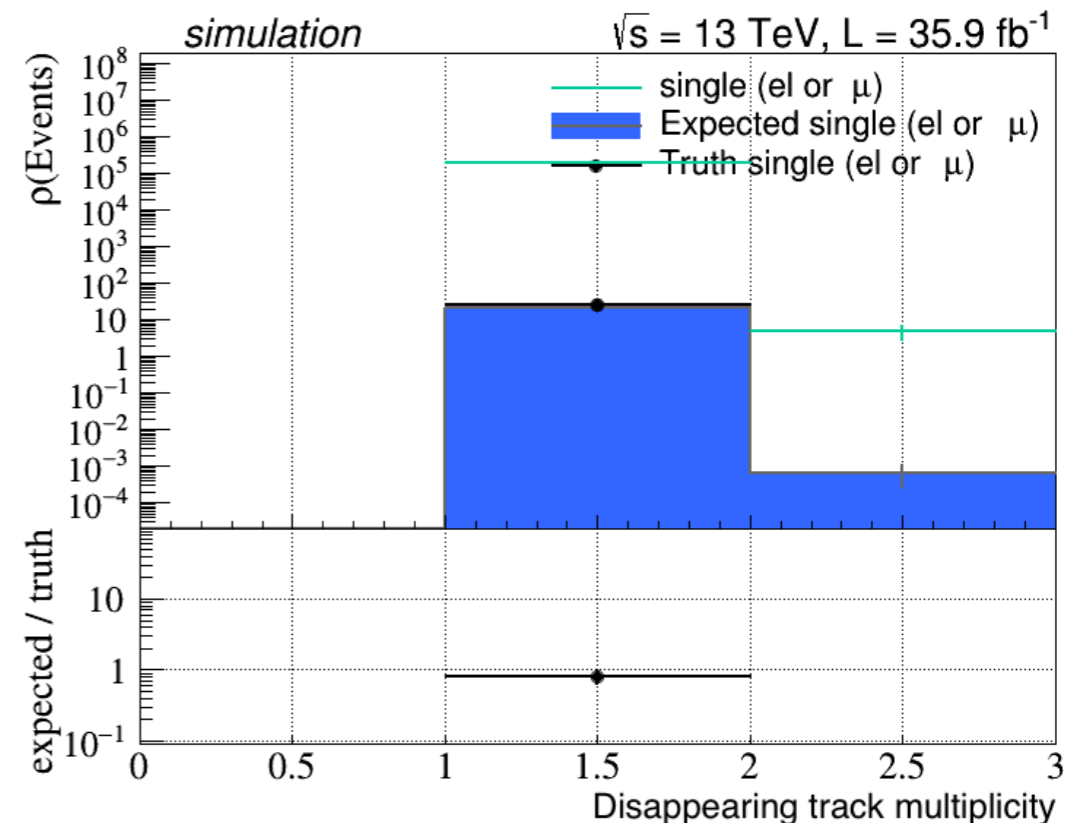

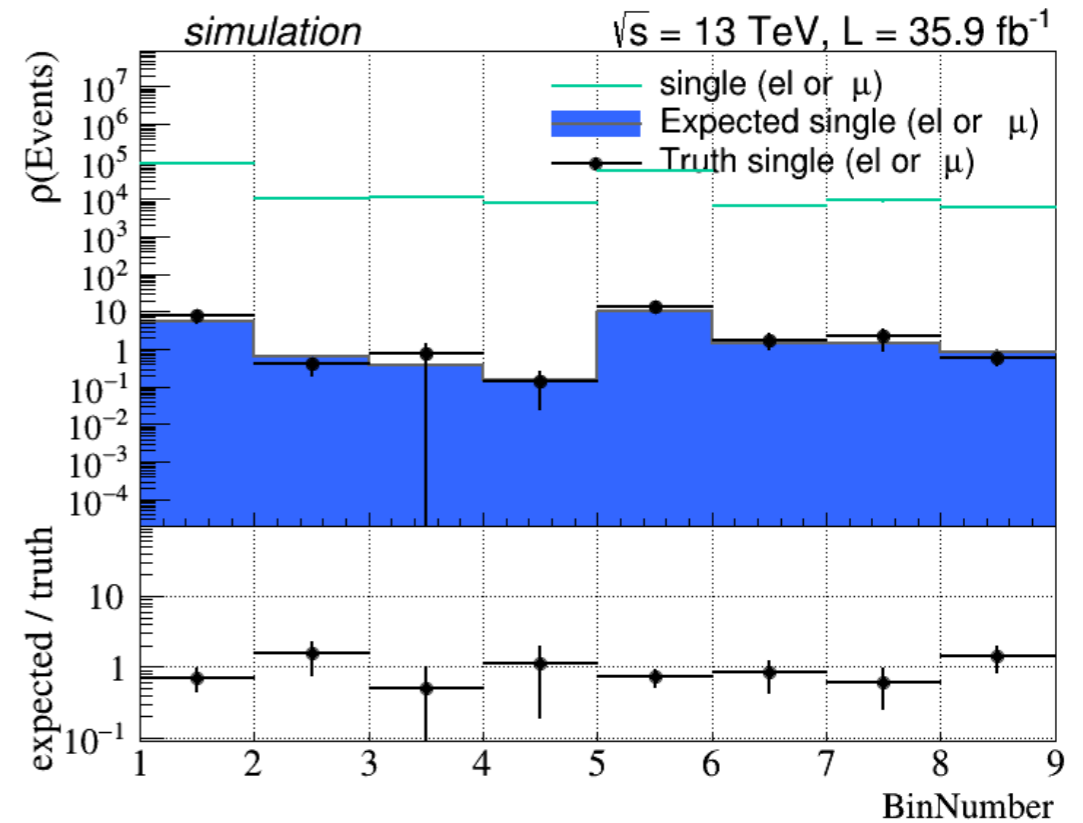

# Kappa values in simulation and Data

- Kappa for electrons in simulation;  $W$ +jets and Drell-Yann (top);
- Kappa is independent of event dynamics;
- Tag-and-probe method is viable method for kappa calculation.
- Kappa for electrons in data (bottom).

# Validation with simulated samples

- Kappa is calculated in Drell-Yann sample with tag-and-probe;
- Validated in  $W$ +jets sample for electrons and muons background;
- Closure in 8 signal regions (top) and disappearing track bins (bottom).

# Fake background estimation

- Estimated using a transfer factor alpha measured in pure Drell-Yann events selected as:
  - Number of muons = 2 with  $p_T > 30$  GeV and  $|\eta| < 2.4$
  - Both muons pass tight muon ID
  - $\mu_{\text{charge}}^1 + \mu_{\text{charge}}^2 = 0$
  - $|\text{IM}_{\mu\mu} - M_Z| < 10$  GeV
- Any track except for those from muons is a fake track.

# Alpha calculation

- A ‘control region fake track’ and a ‘signal region fake track’ are defined depending on impact parameter:
- ‘Control region fake track’:  $|d_{xy}| < 0.01$  cm
- ‘Signal region fake track’ :  $0.02 < |d_{xy}| < 0.1$  cm

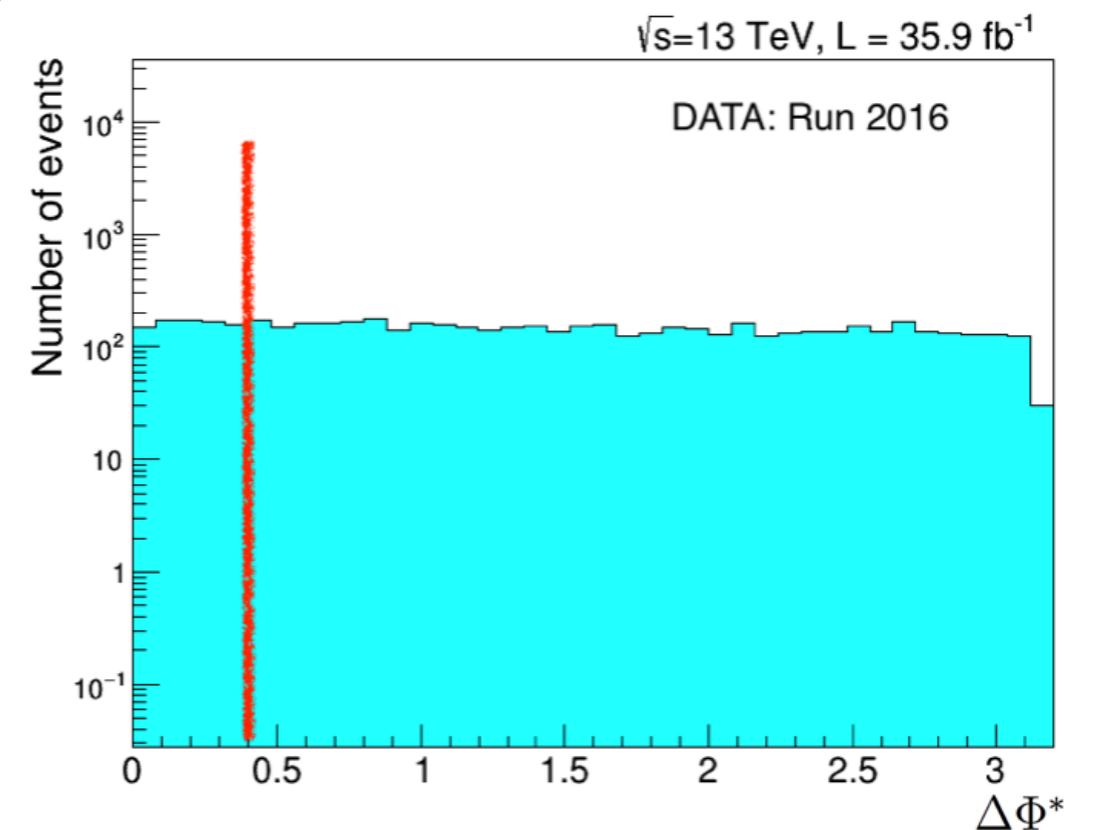

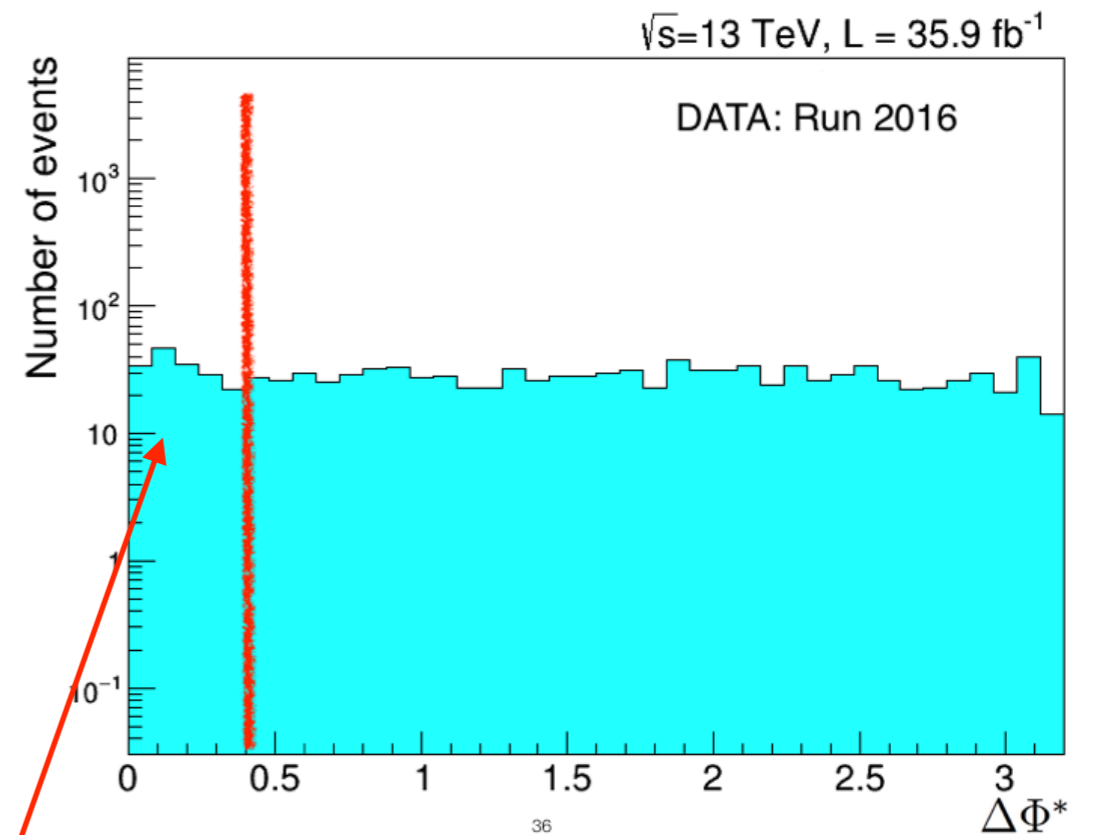

$$\alpha = \frac{N_{(|d_{xy}|<0.01)}}{N_{(0.02<|d_{xy}|<0.1)}}$$

- Estimate ‘signal region fake tracks’ in signal regions as:

$$N_{(|d_{xy}|<0.01)} = \alpha \times N_{(0.02<|d_{xy}|<0.1)}$$

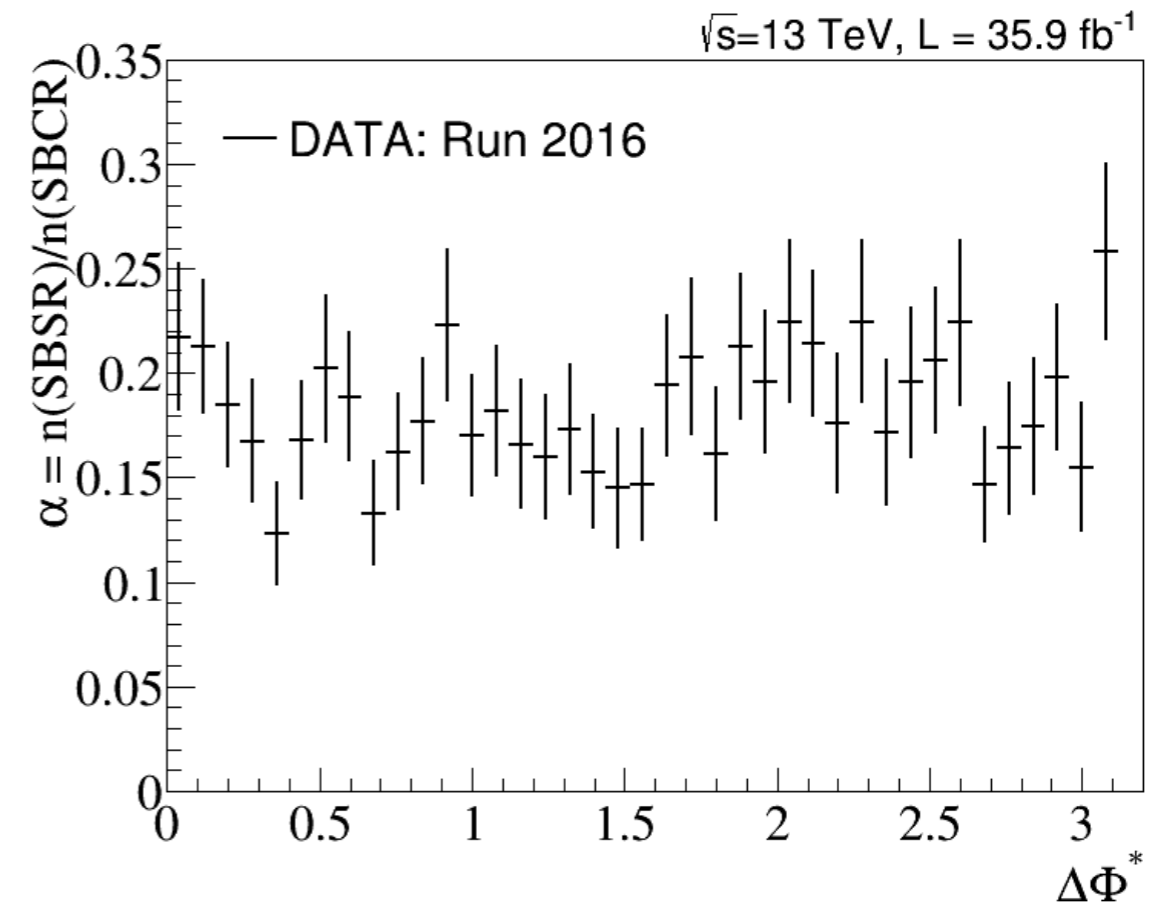

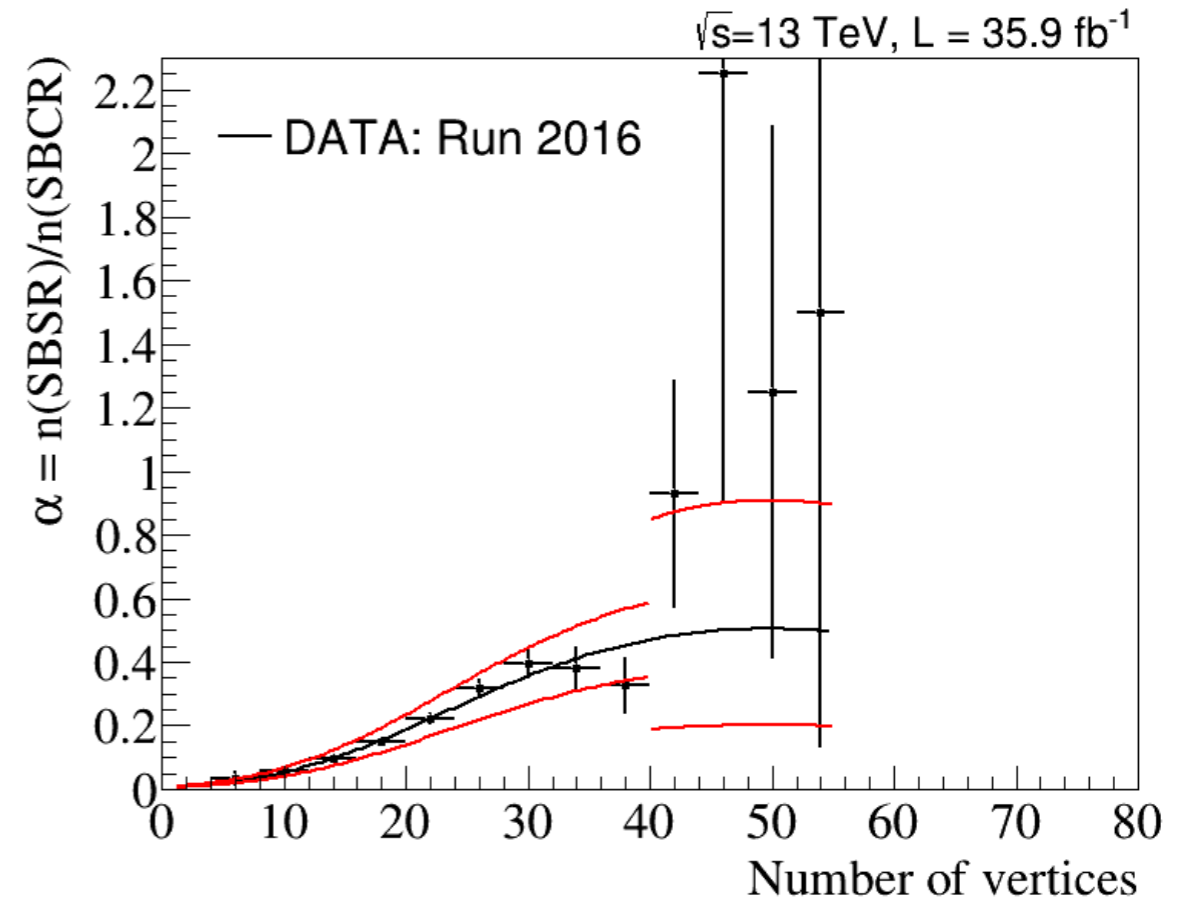

# Alpha calculation

- Estimation in Drell-Yann events in data; distribution of disappearing tracks in data
- ‘Signal region fake track’ distribution (top)
- ‘Control region fake track distribution’ (bottom)
- Alpha calculated only in the events with  $\Delta\Phi^* > 0.4$
- Prompt tracks peak at  $\Delta\Phi \rightarrow 0$

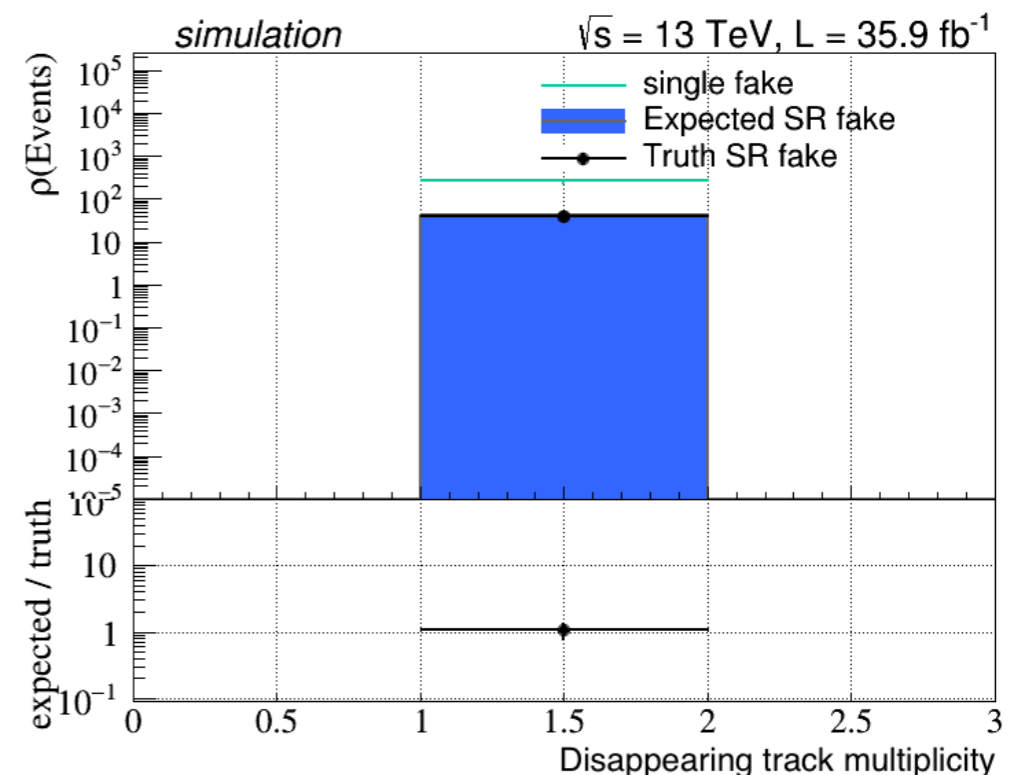

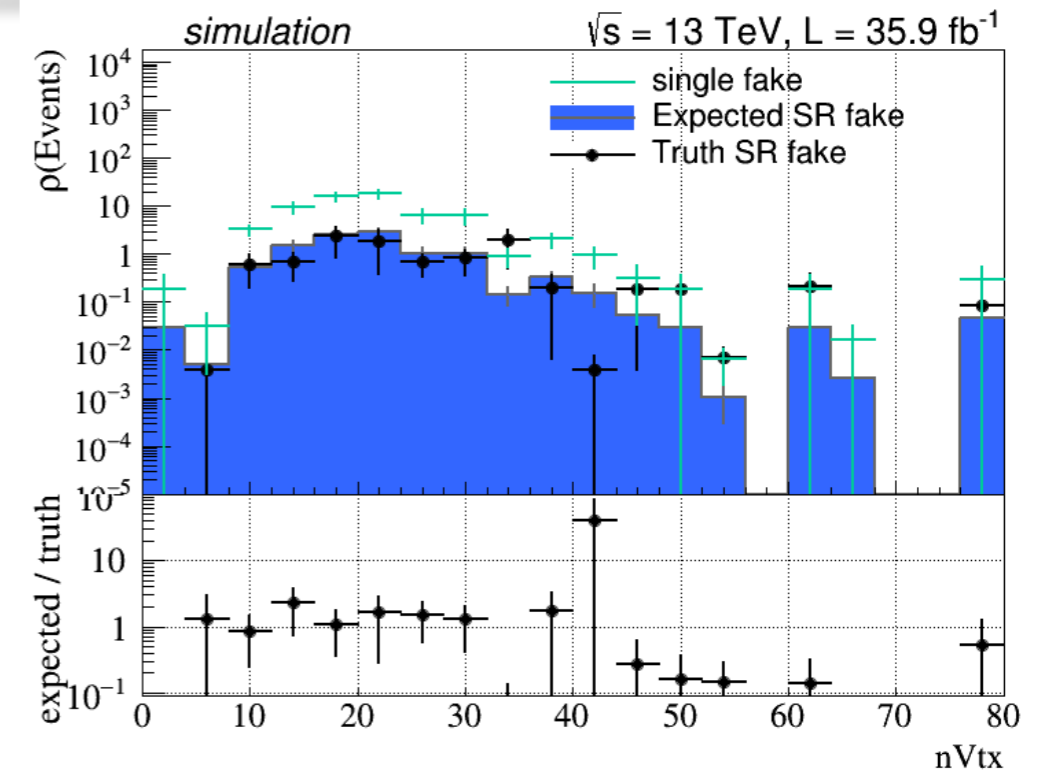

# Alpha values

- Fake tracks originate from pileup tracks and noise
- Alpha as a function of number of verticals is used for background estimation
- Alpha almost constant in other variables
- Alpha values as a function of  $R$ .

# Validation with simulated samples

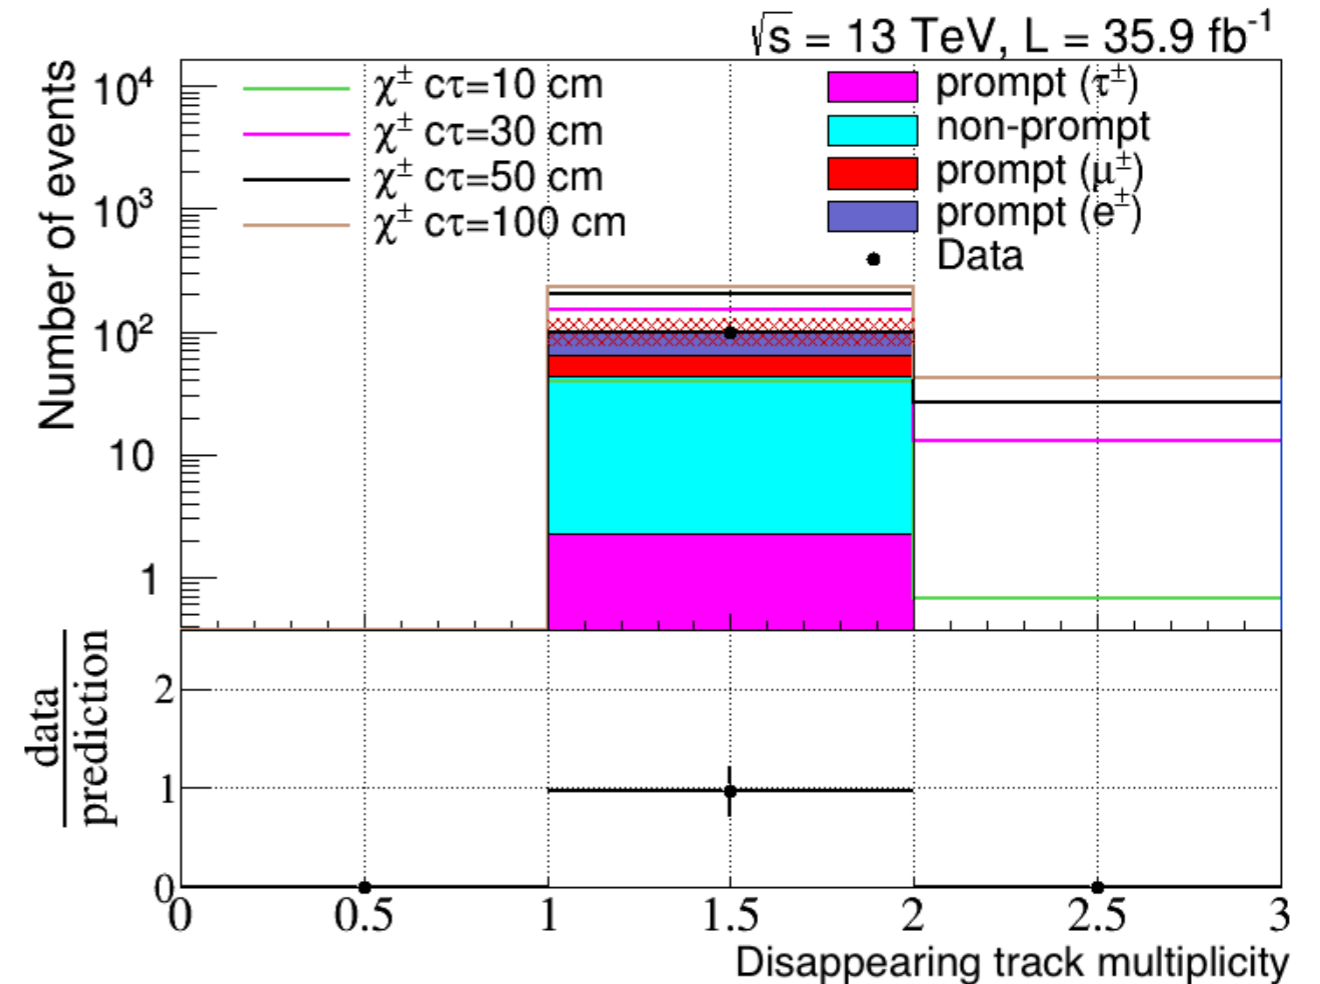

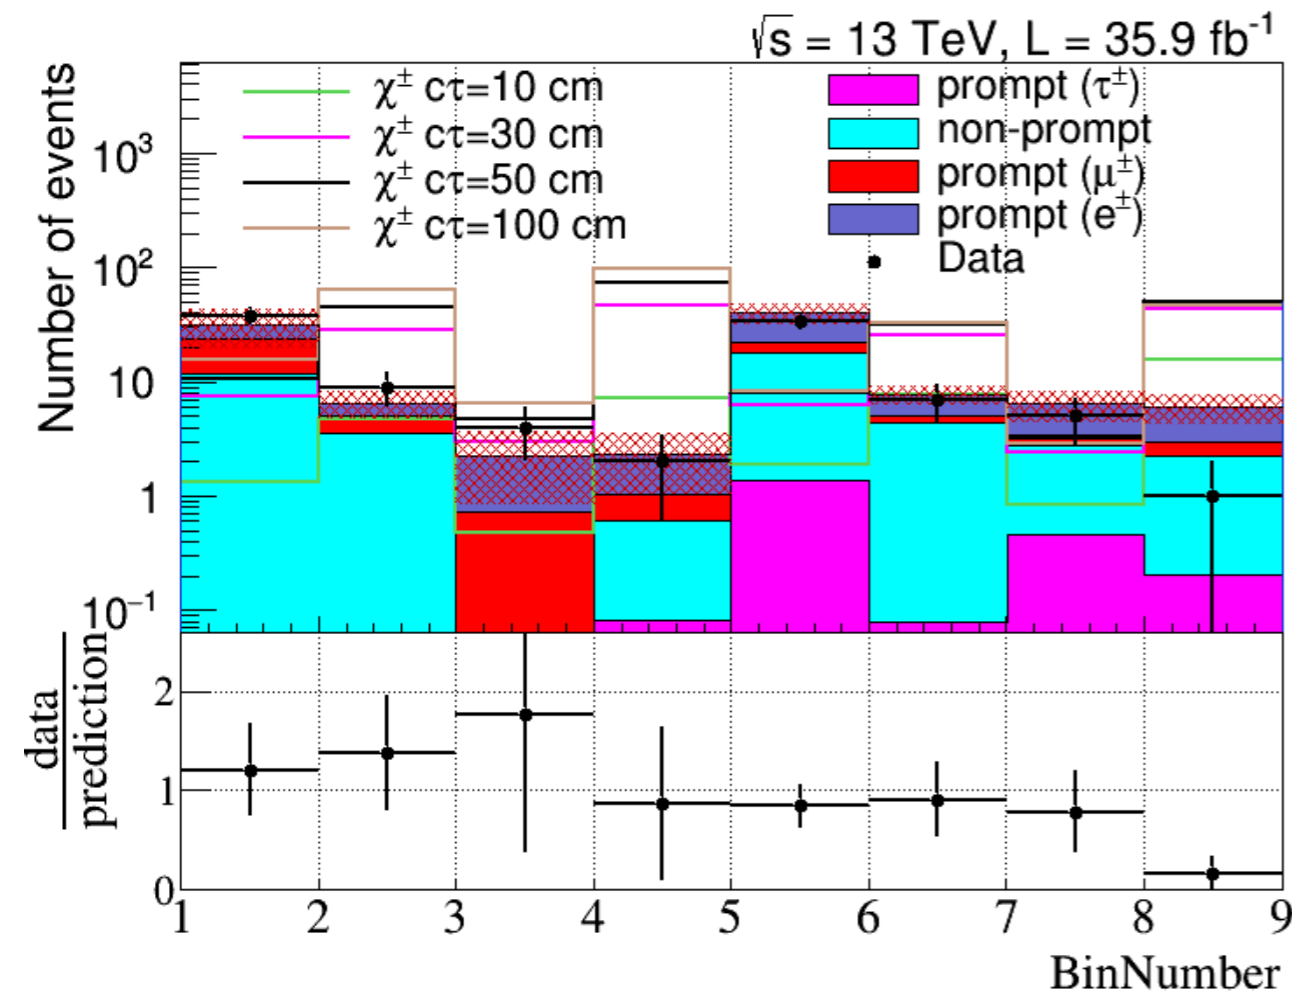

- Alpha measured in Drell-Yann events;
- Estimation validated in  $t$ - $t$ bar, QCD, and  $W$ -jets.
- Signal region: number of vertices (top).
- Signal region: in bins of disappearing track multiplicity.

# Background with two tracks

- Both fake tracks:
  - Weigh a two CR fake track event by  $\alpha*\alpha$
- Both leptonic tracks:
  - Weigh a one lepton and a disappearing track event by  $\kappa$ ; assuming the disappearing track is leptonic
- One fake and one leptonic track:
  - Counted in both leptonic category where the disappearing track is a fake;
  - For separate counts; weigh the two lepton region by  $\kappa*\kappa$  and subtract from the combined counts.

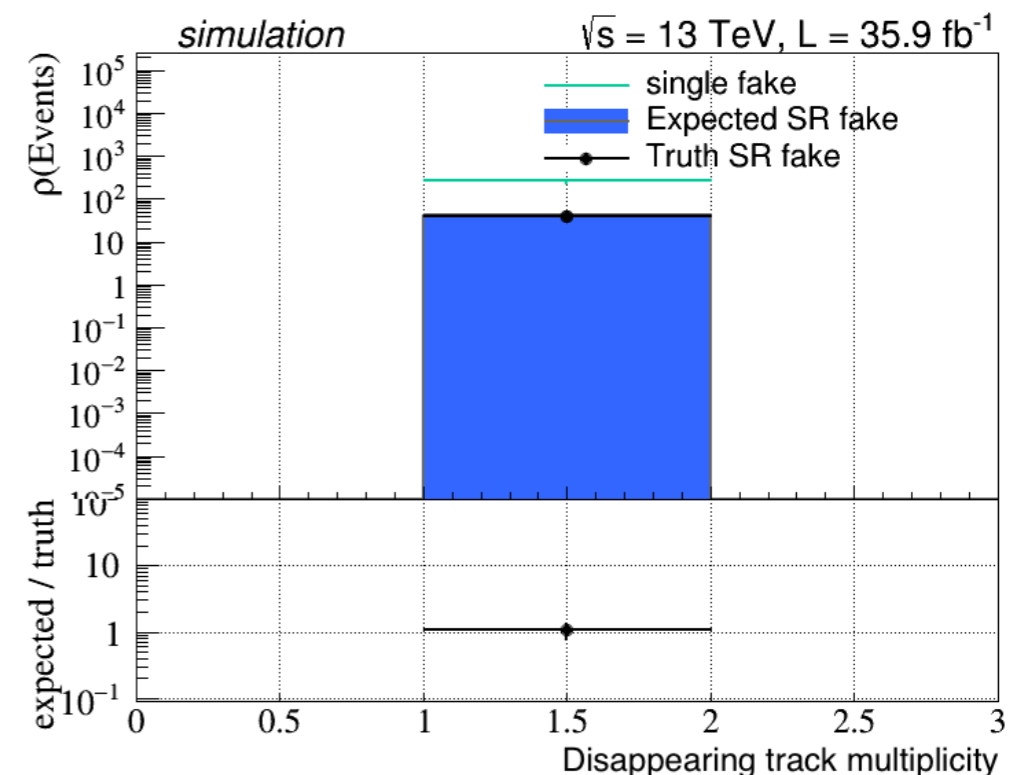

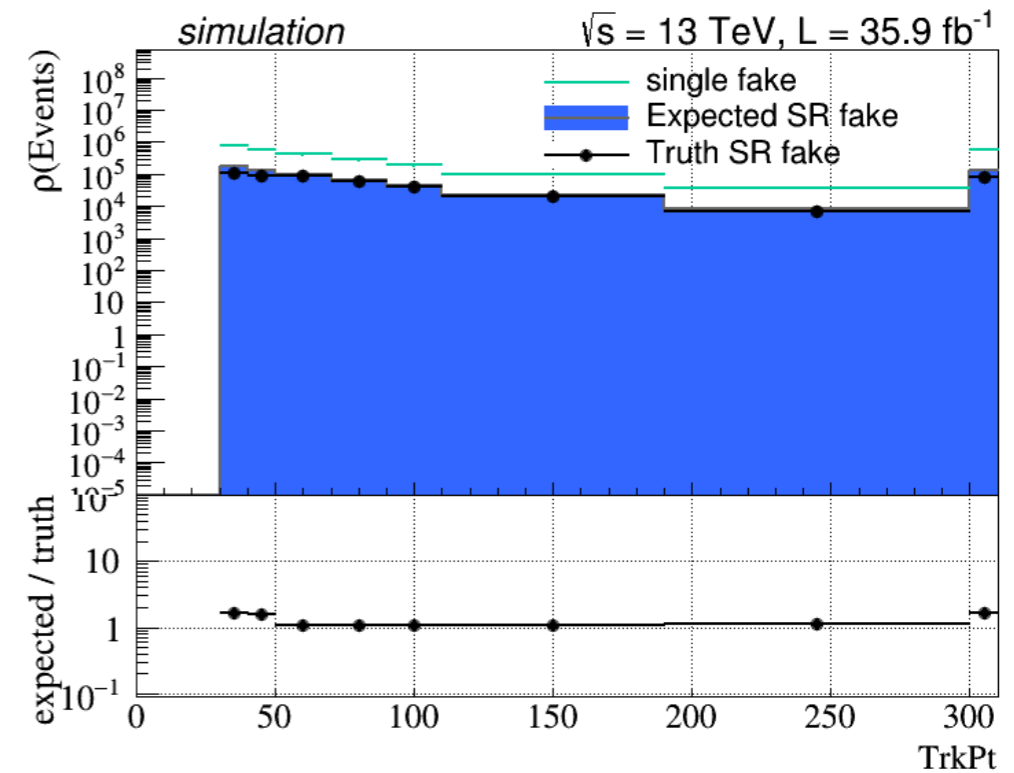

# Prediction and Observation

- Systematic uncertainties; fit parameters varied in their uncertainties.
- No significant excess; limits to be set using profile likelihood ratio as test static.

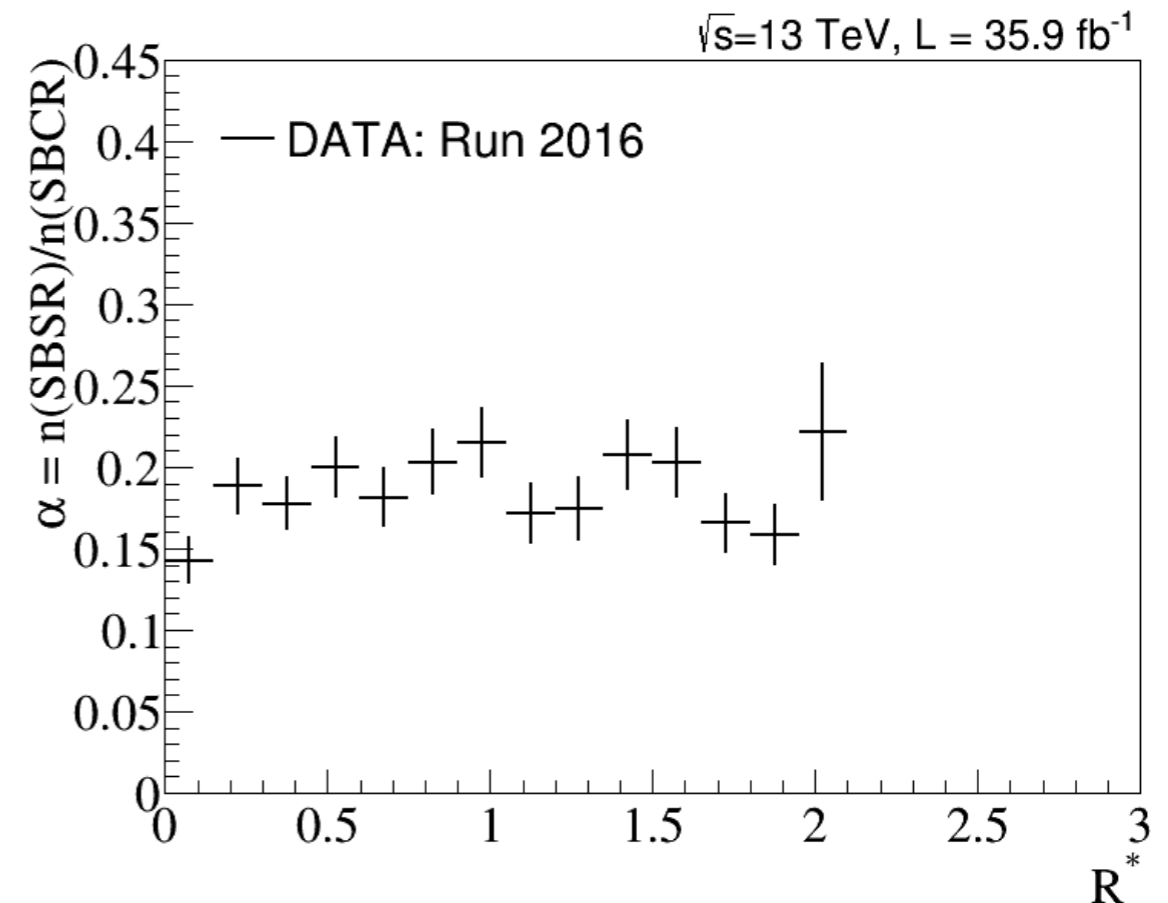

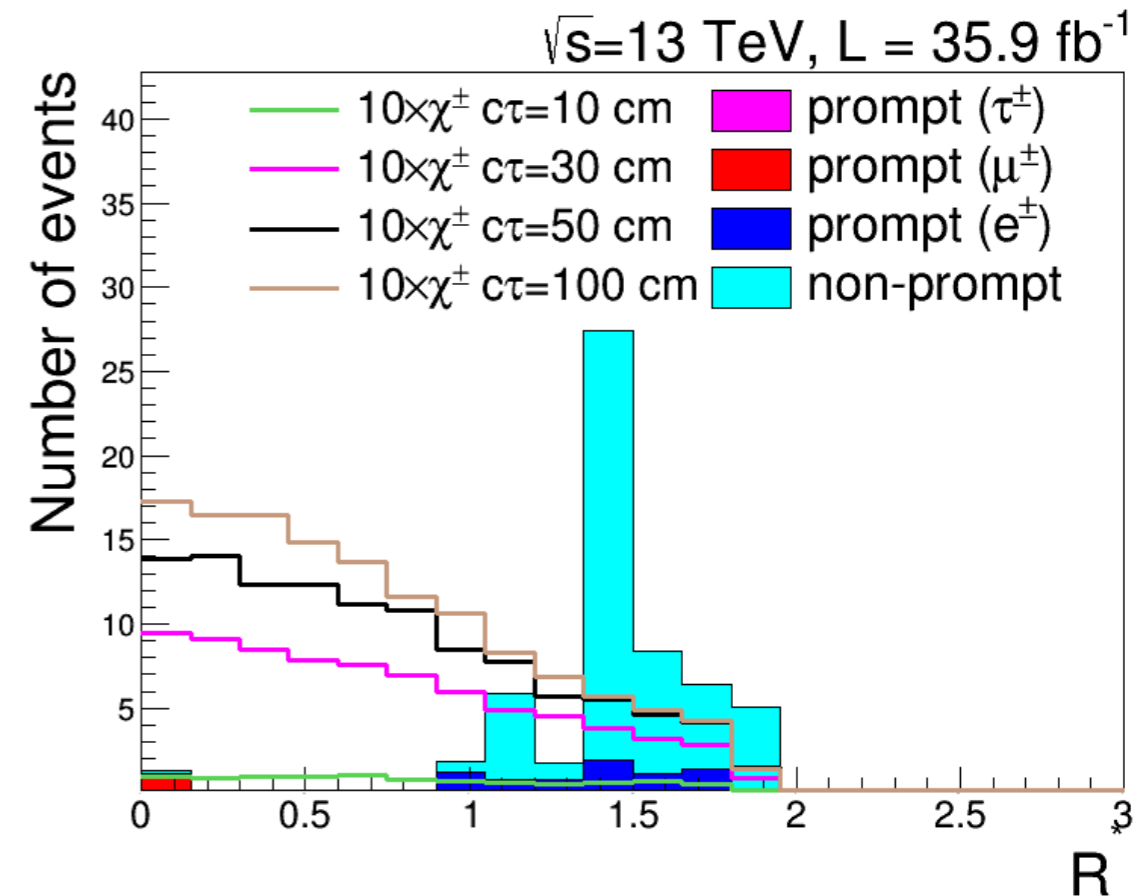

# Validation with simulated samples

- Alpha measured in Drell-Yann events;
- Estimation validated in  $t$ - $t$ bar, QCD, and  $W$ -jets.
- No cuts: in track Pt bins (top).
- Signal region: in bins of disappearing track multiplicity.

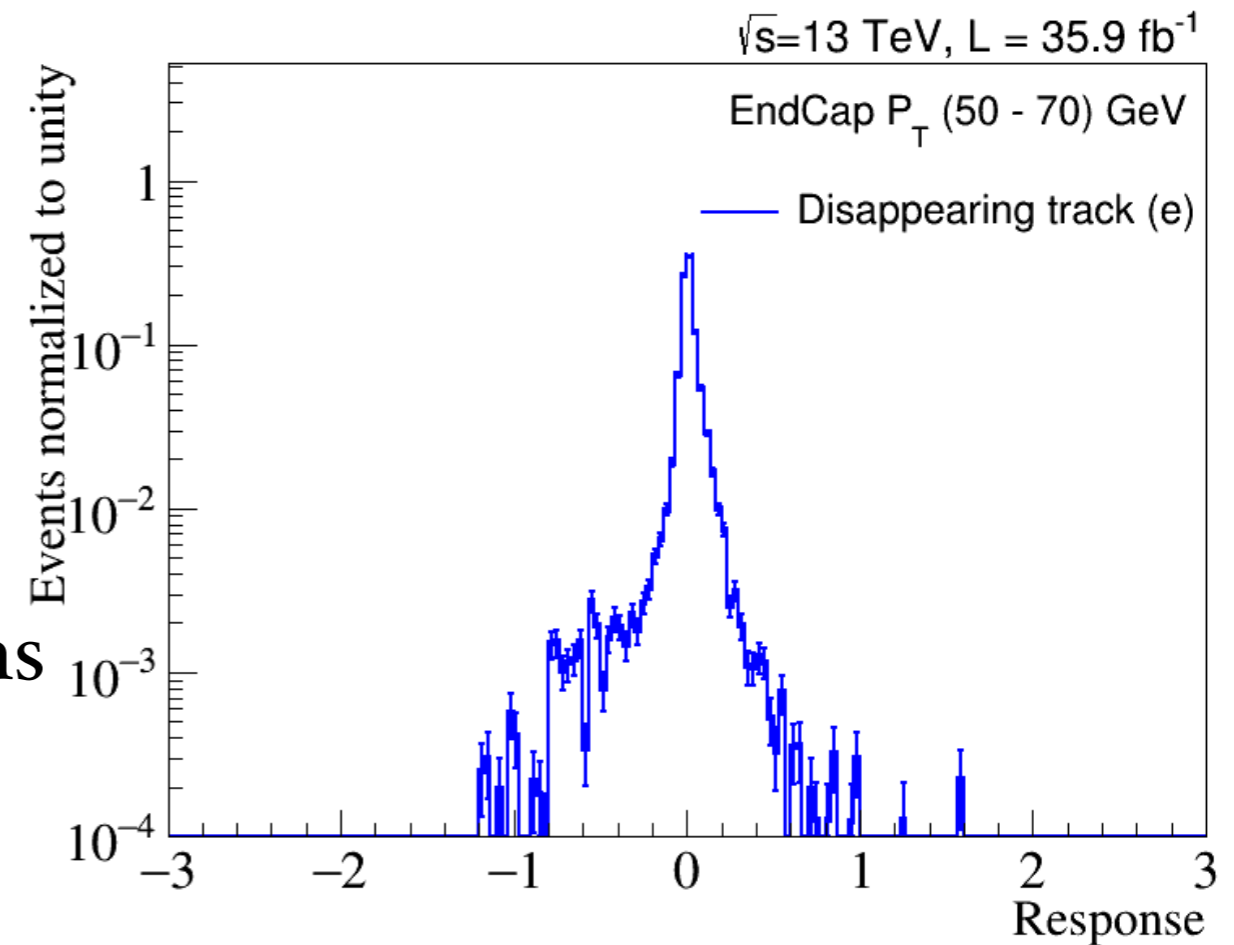

# Alpha values

- Fake tracks originate from pileup tracks and noise
- Alpha as a function of number of verticals is used for background estimation
- Alpha almost constant in other variables
- Alpha values as a function of  $R$ .

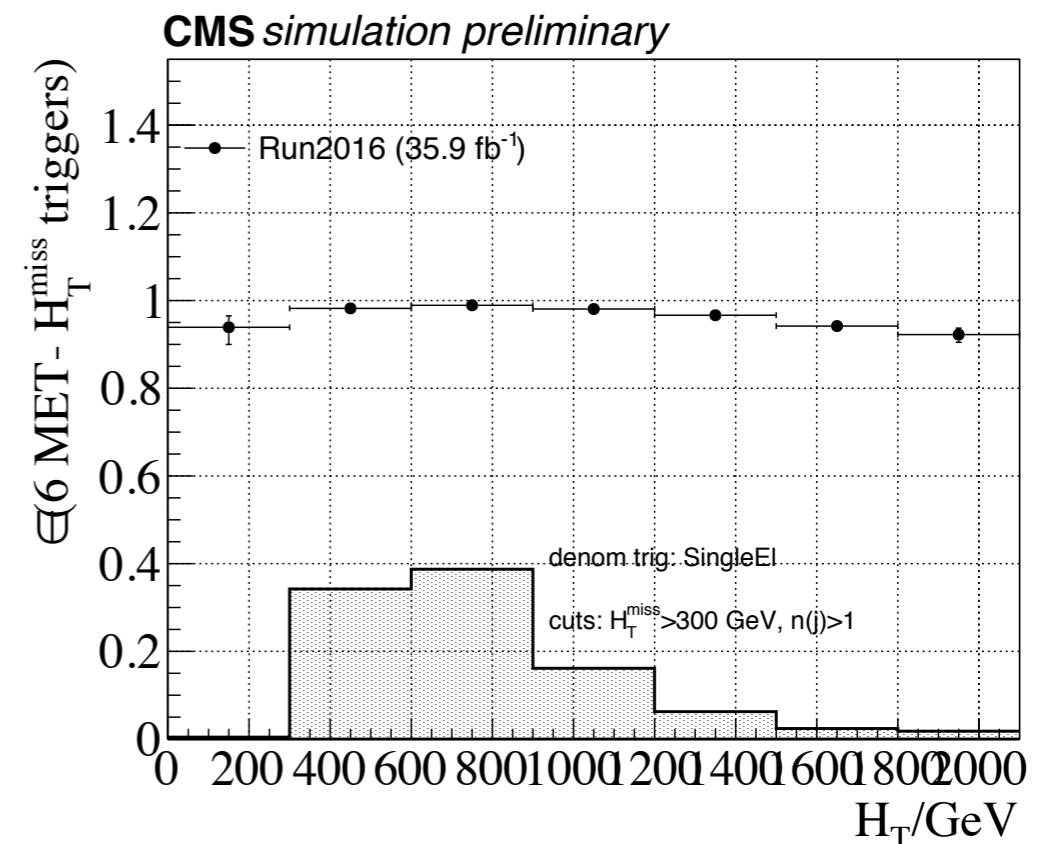

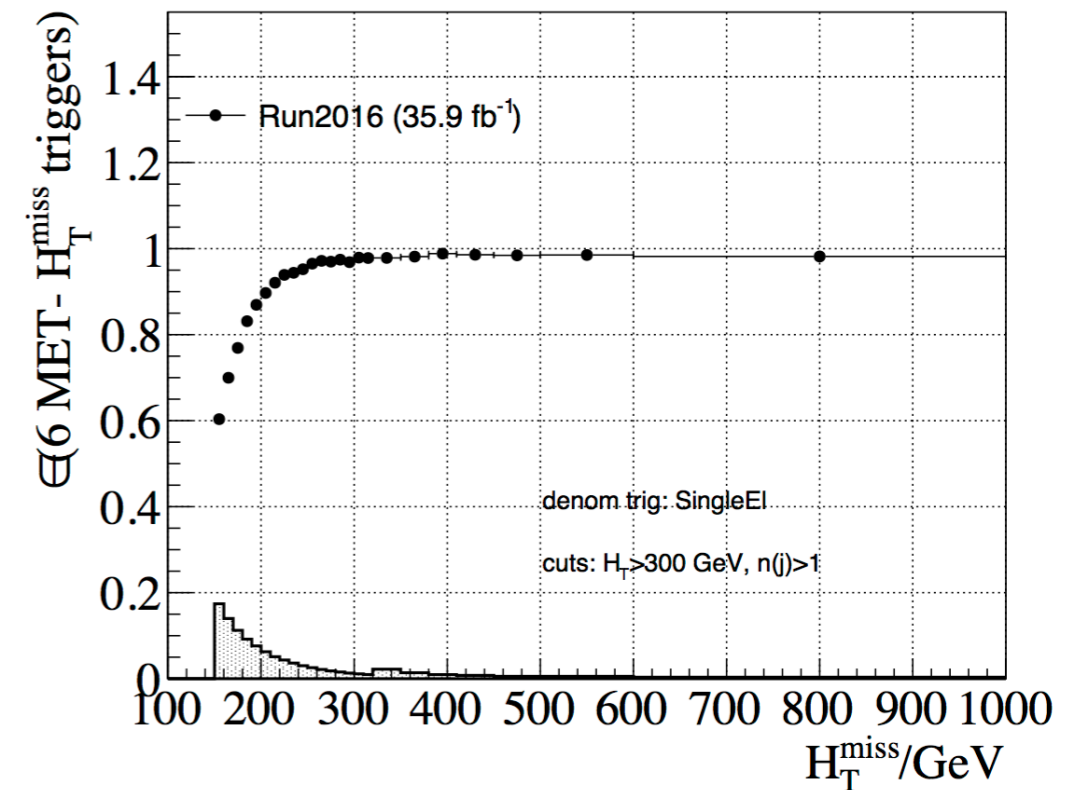

# Probe lepton smearing in data

- Tracker hits of the reconstructed lepton are removed in RECO dataset and reconstruction is run again;
- The original Pt is taken as true Pt.
- Smearing templates are made in bins of number of missing outer hits;
- Normalized by missing outer hits distribution of disappearing tracks in data.

# Trigger selection

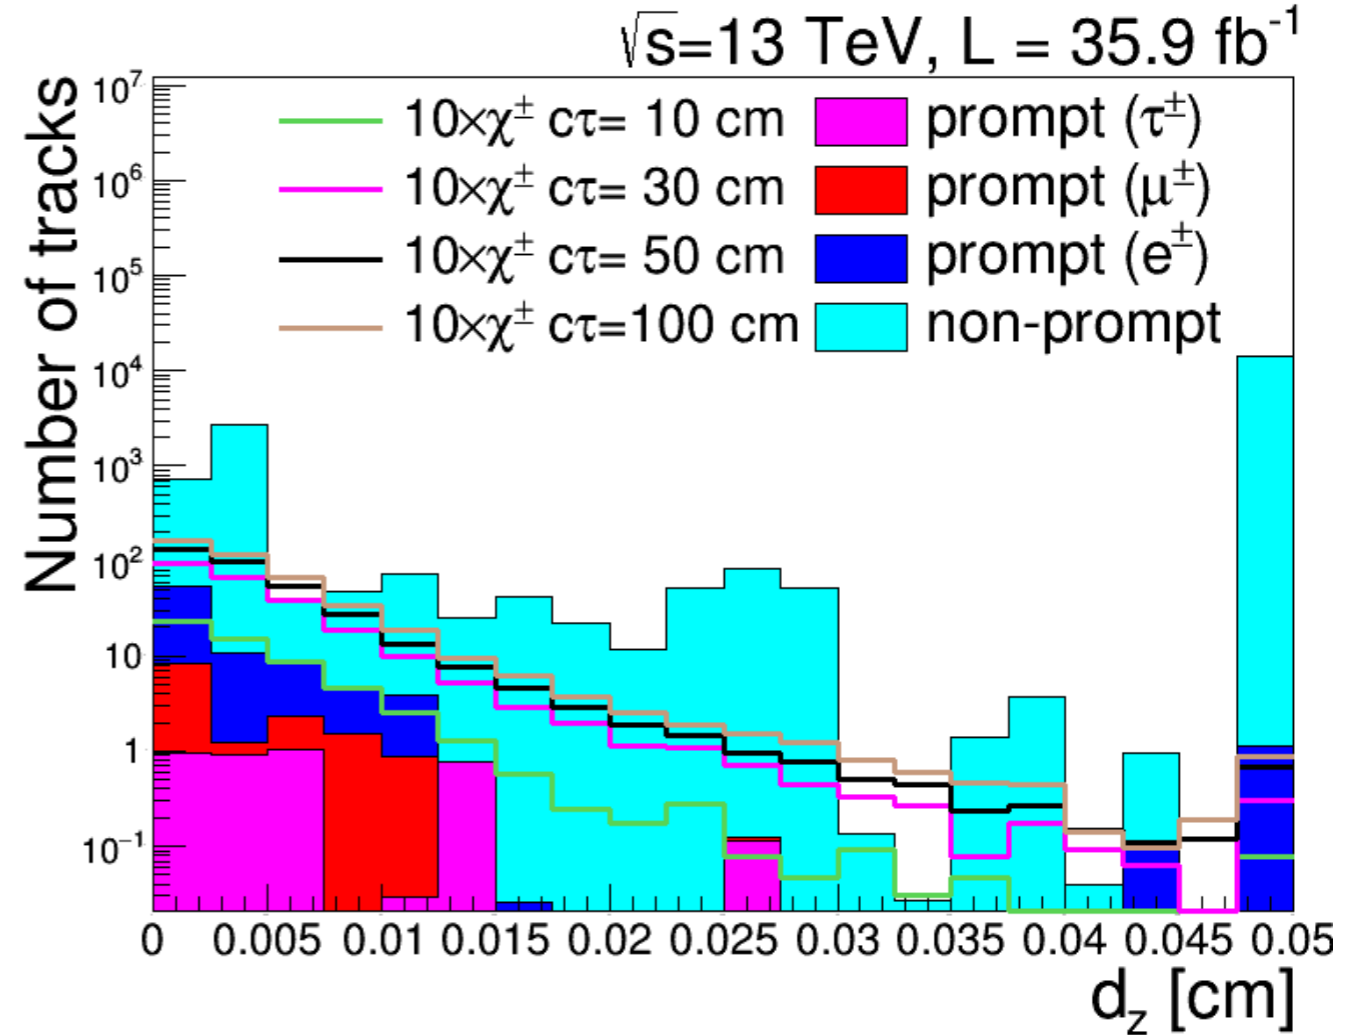

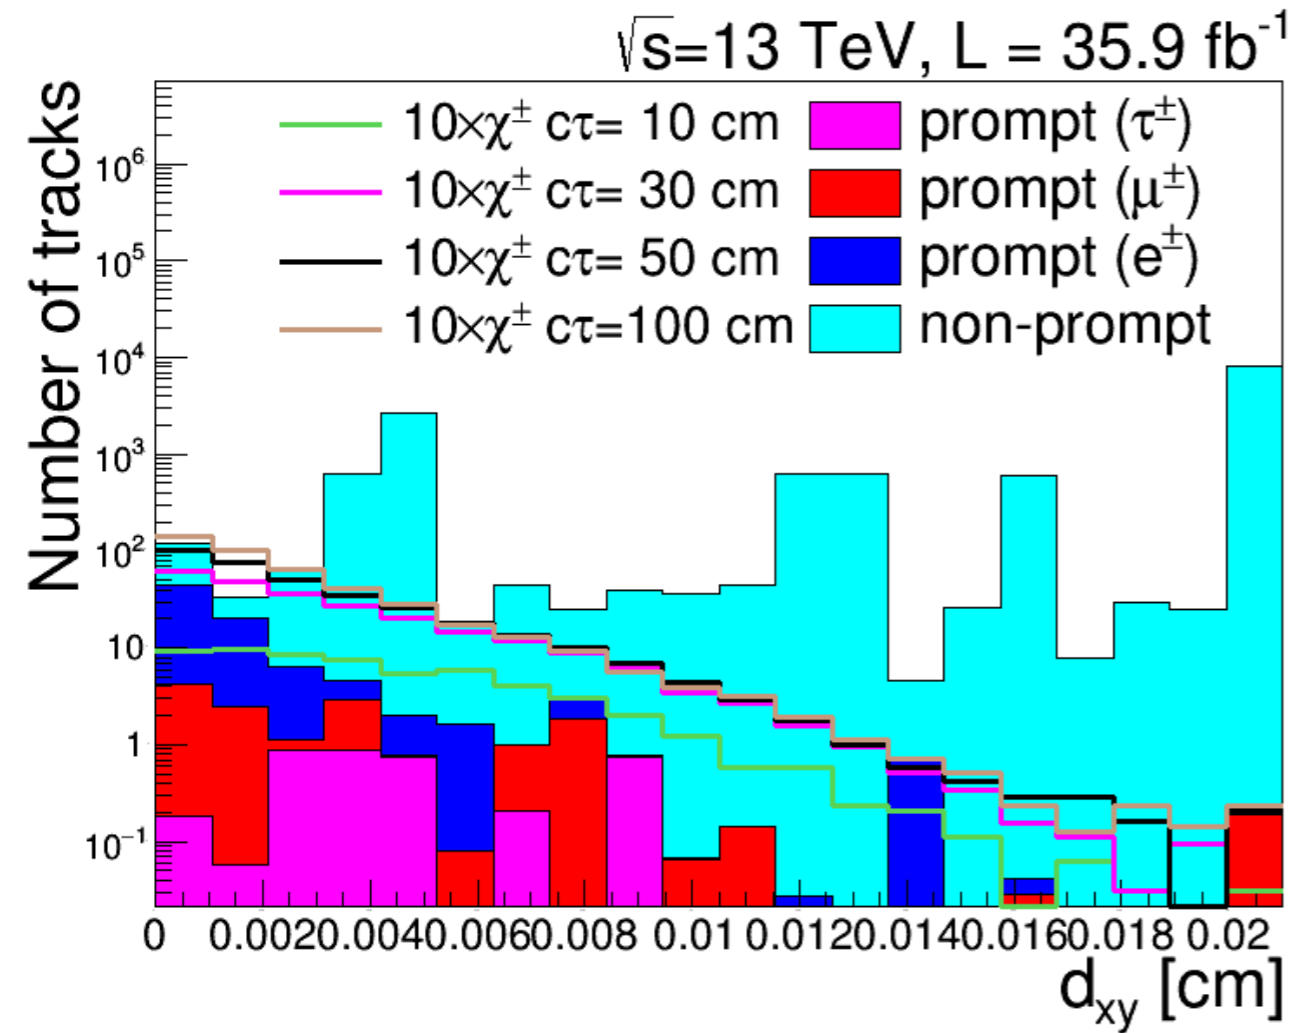

- 6 MET-MHT trigger
- Trigger efficiencies at event selections
- $> 97\%$  for  $MHT > 250$ .
- $> 98\%$  for  $HT > 350$ .

# Object Definitions

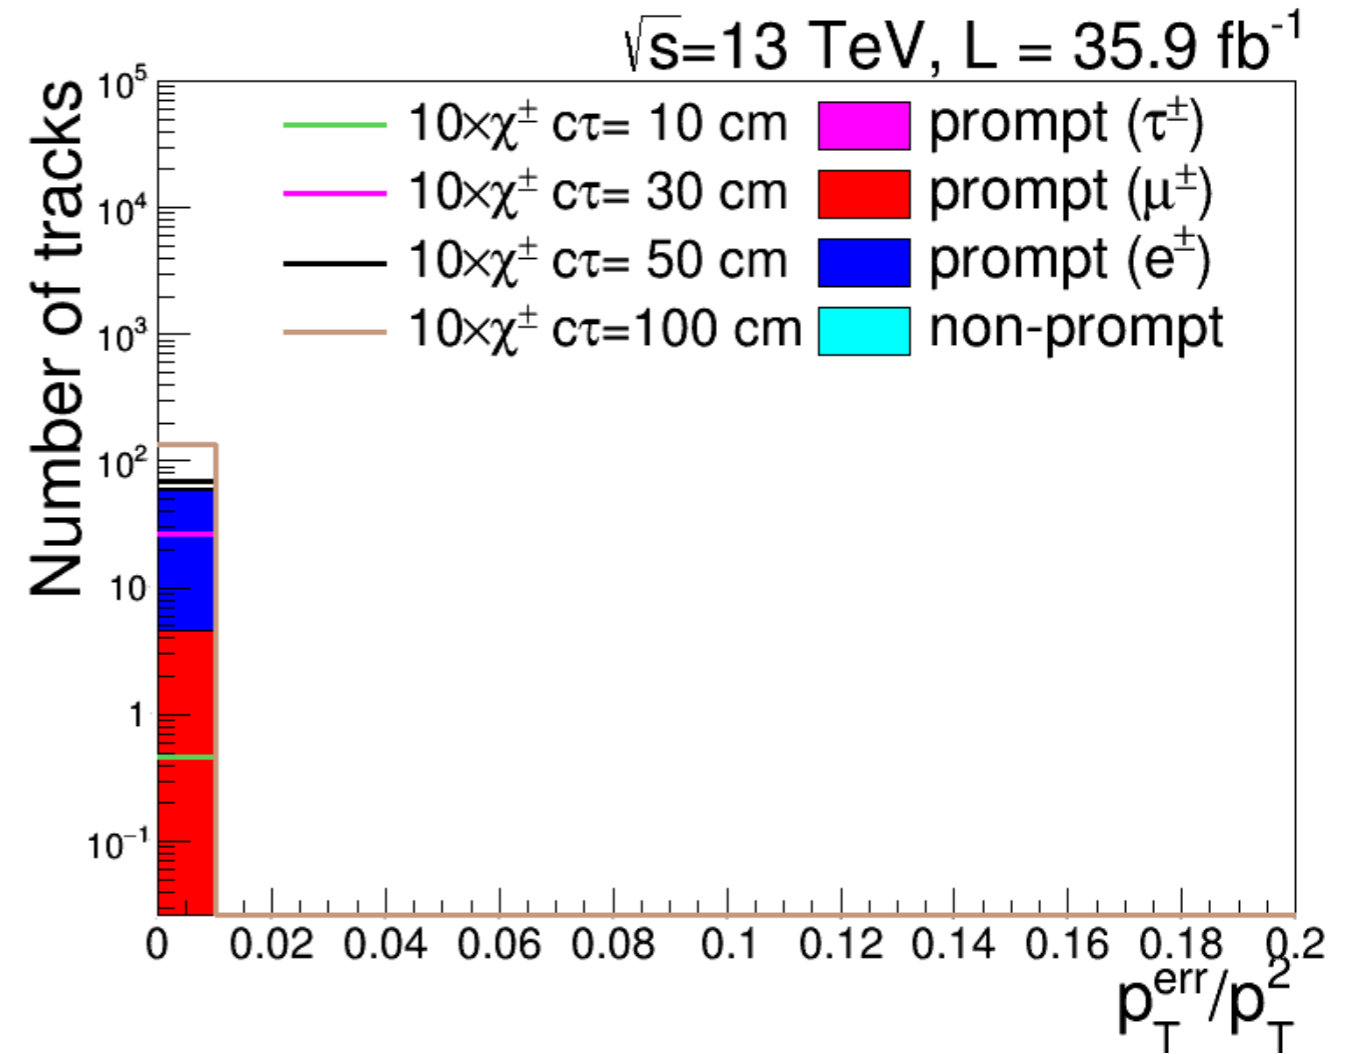

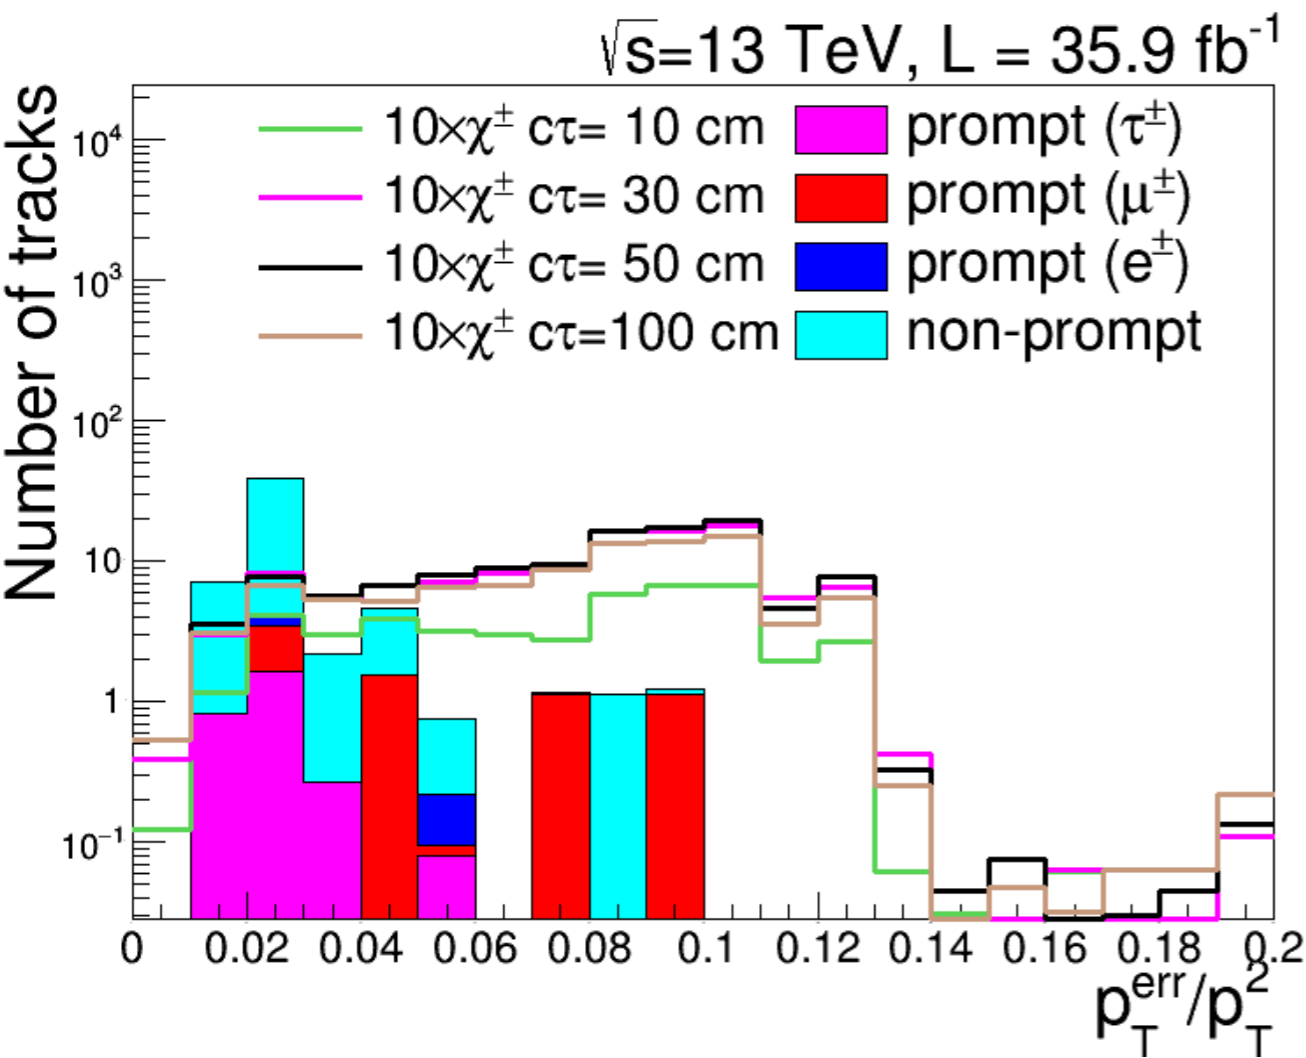

- Baseline track
  - Track  $p_T > 30$  GeV
  - Track  $|\eta| < 1.442$  or  $1.566 < |\eta| < 2.4$
  - Flagged as a high purity track
  - Tracker layers of measurement  $\geq 3$
- Disappearing track category:
  - short tracks: tracks with three layers of measurement (pixel only tracks)
  - medium tracks: tracks with  $> 3$  tracker layers of measurement and  $< 7$  tracker layers of measurement
  - long tracks: tracks with  $\geq$  seven tracker layers of measurement.

# Impact parameters

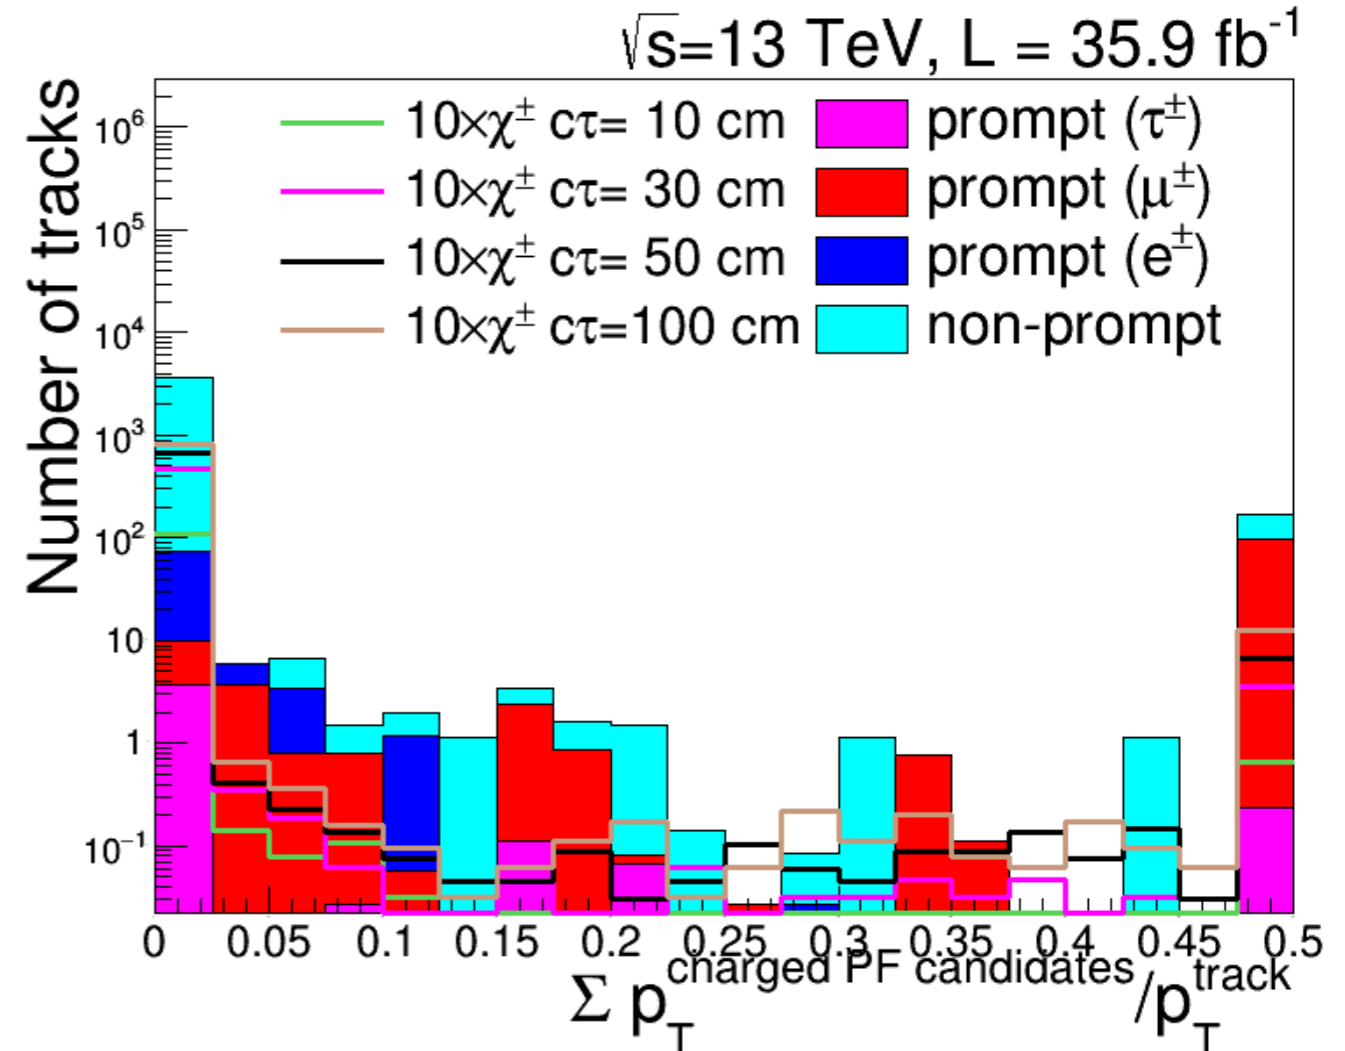

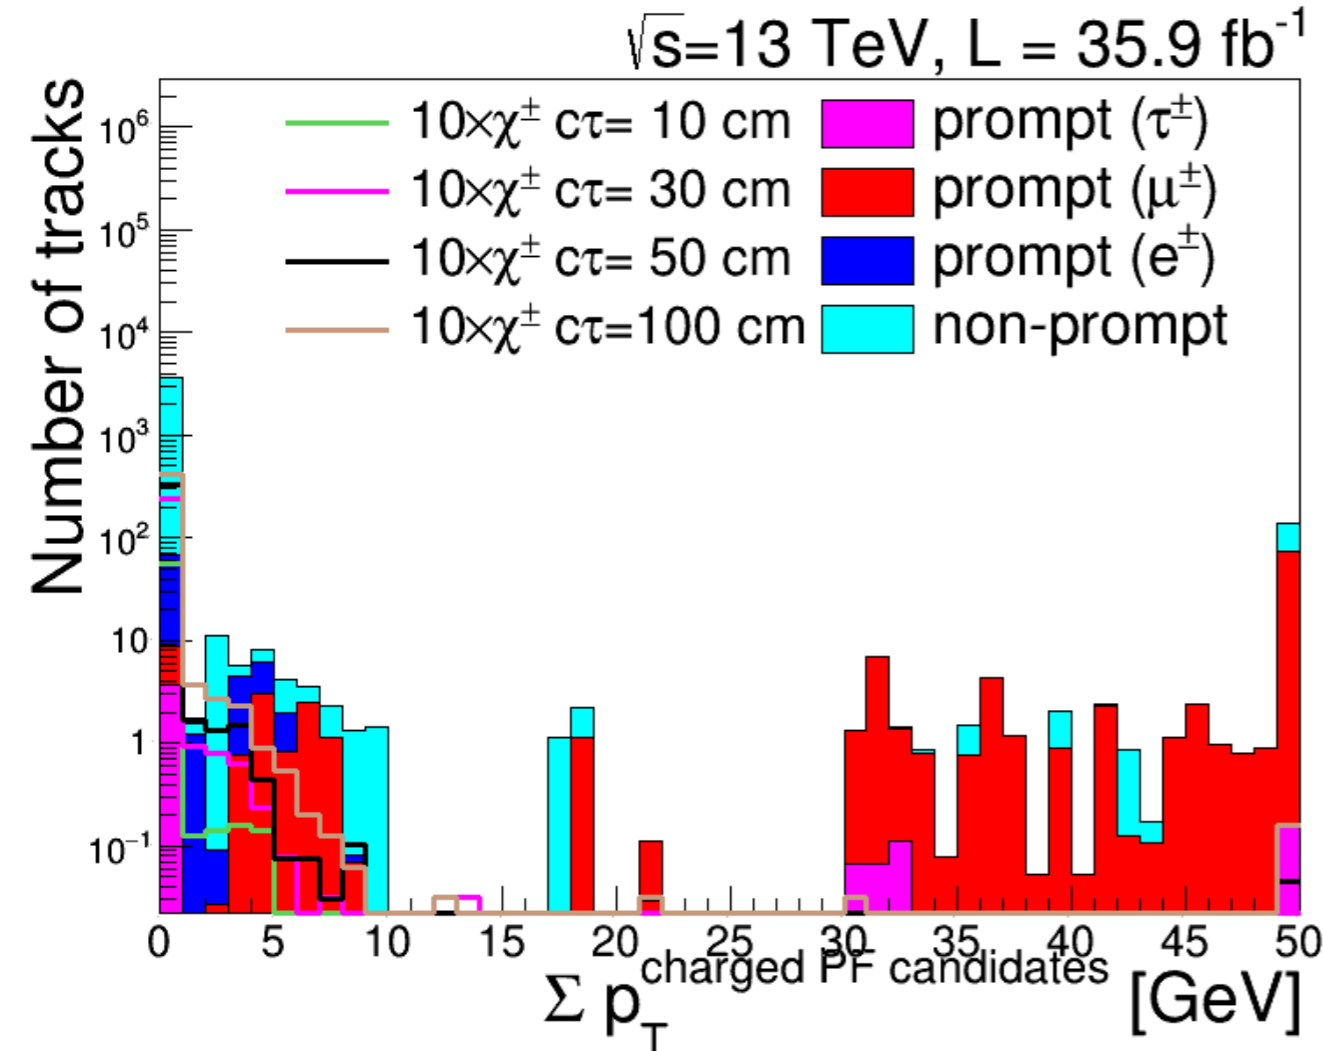

- $d_{xy} < 0.01$  cm and  $d_z < 0.02$  cm

# Track resolution

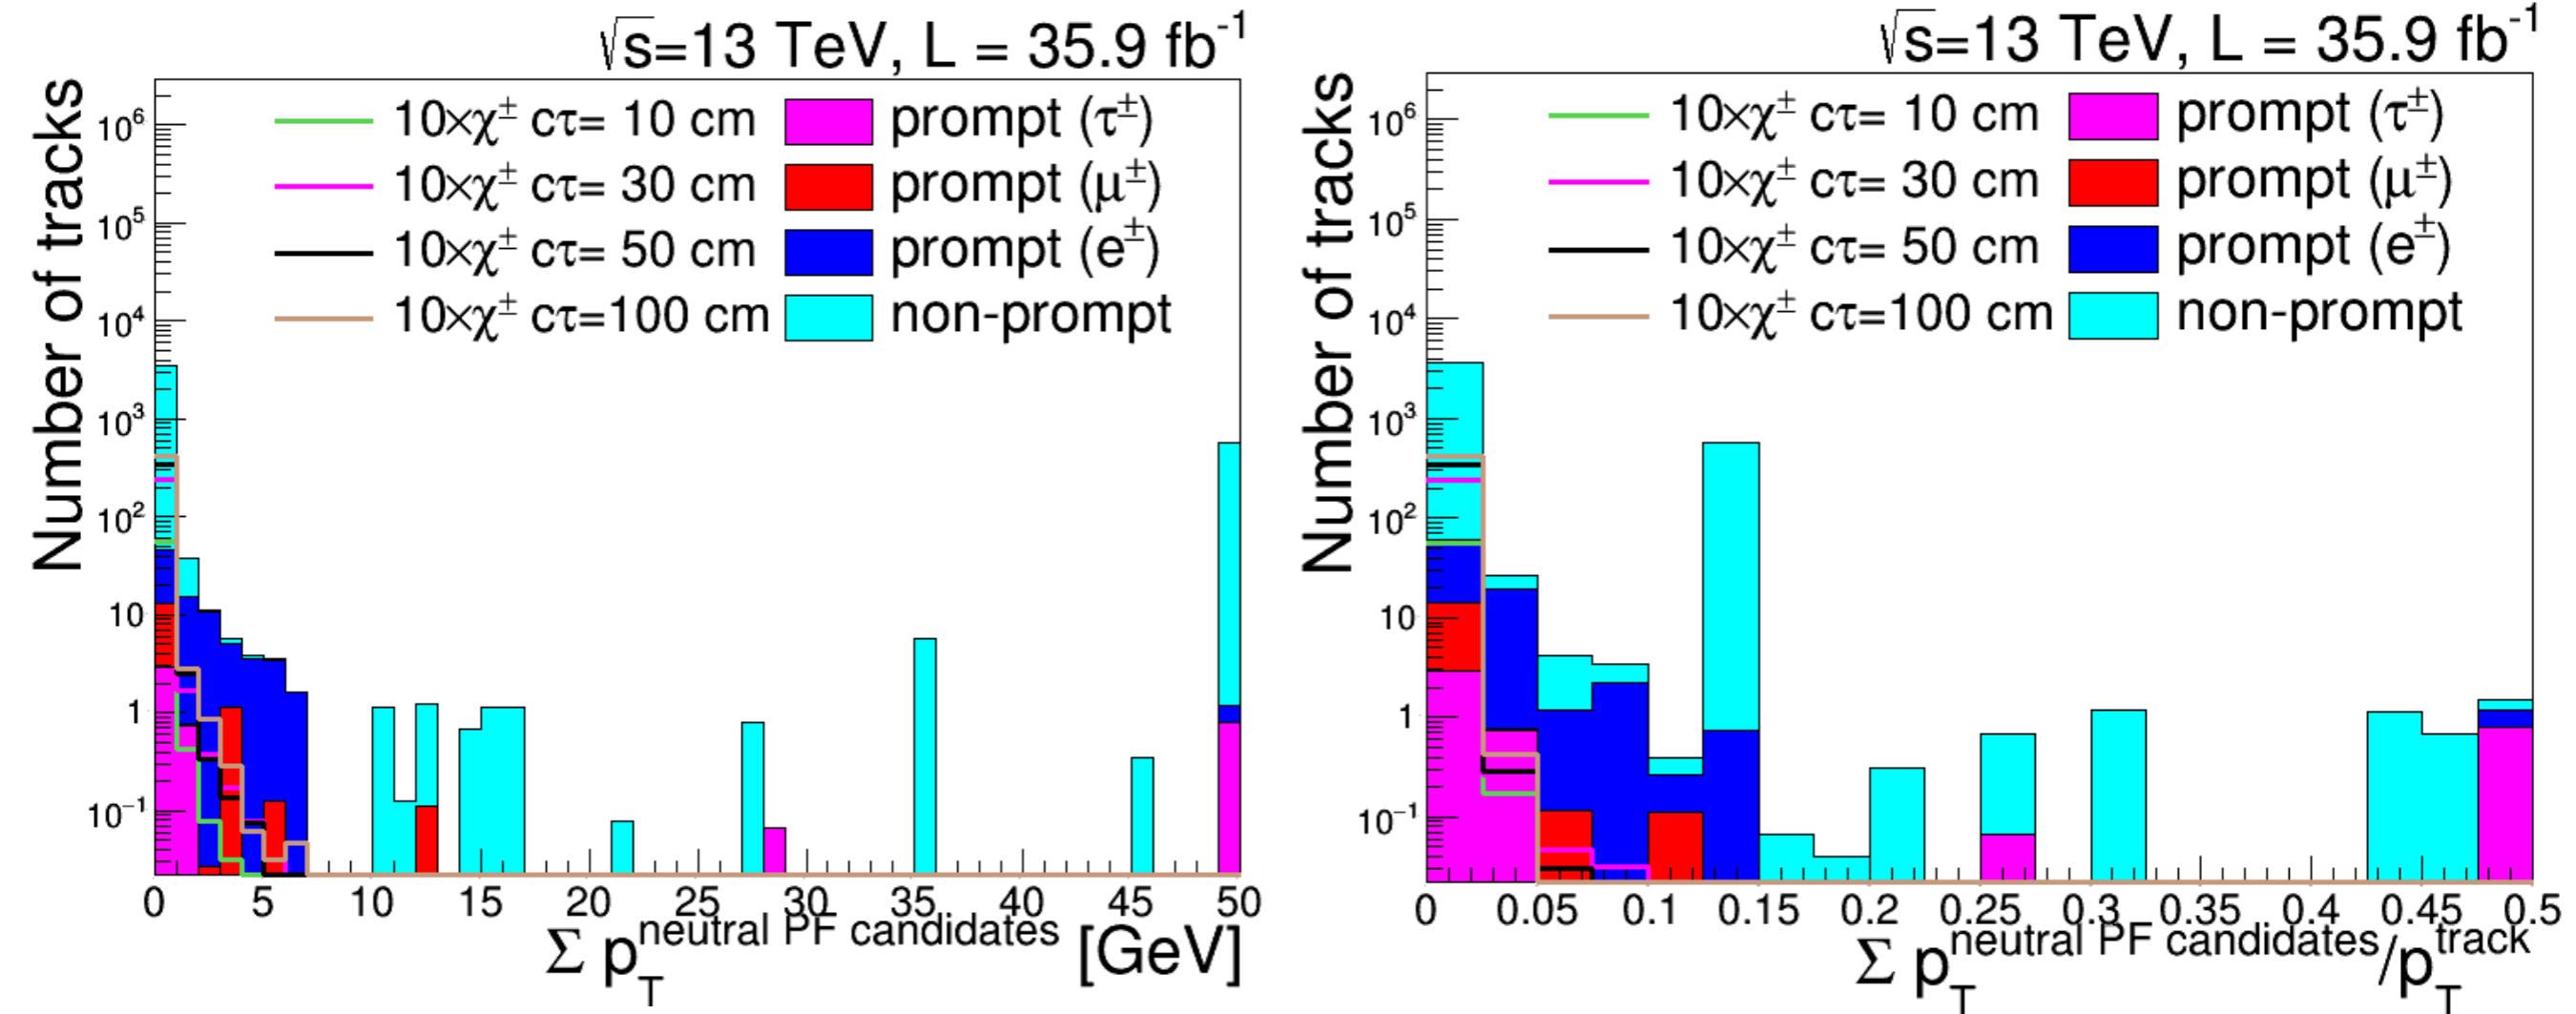

- $p_T^{\text{error}}/p_T^2 < 0.2$  for short ;  $< 0.05$  for medium and  $< 0.02$  for long

# Isolation from charged particles

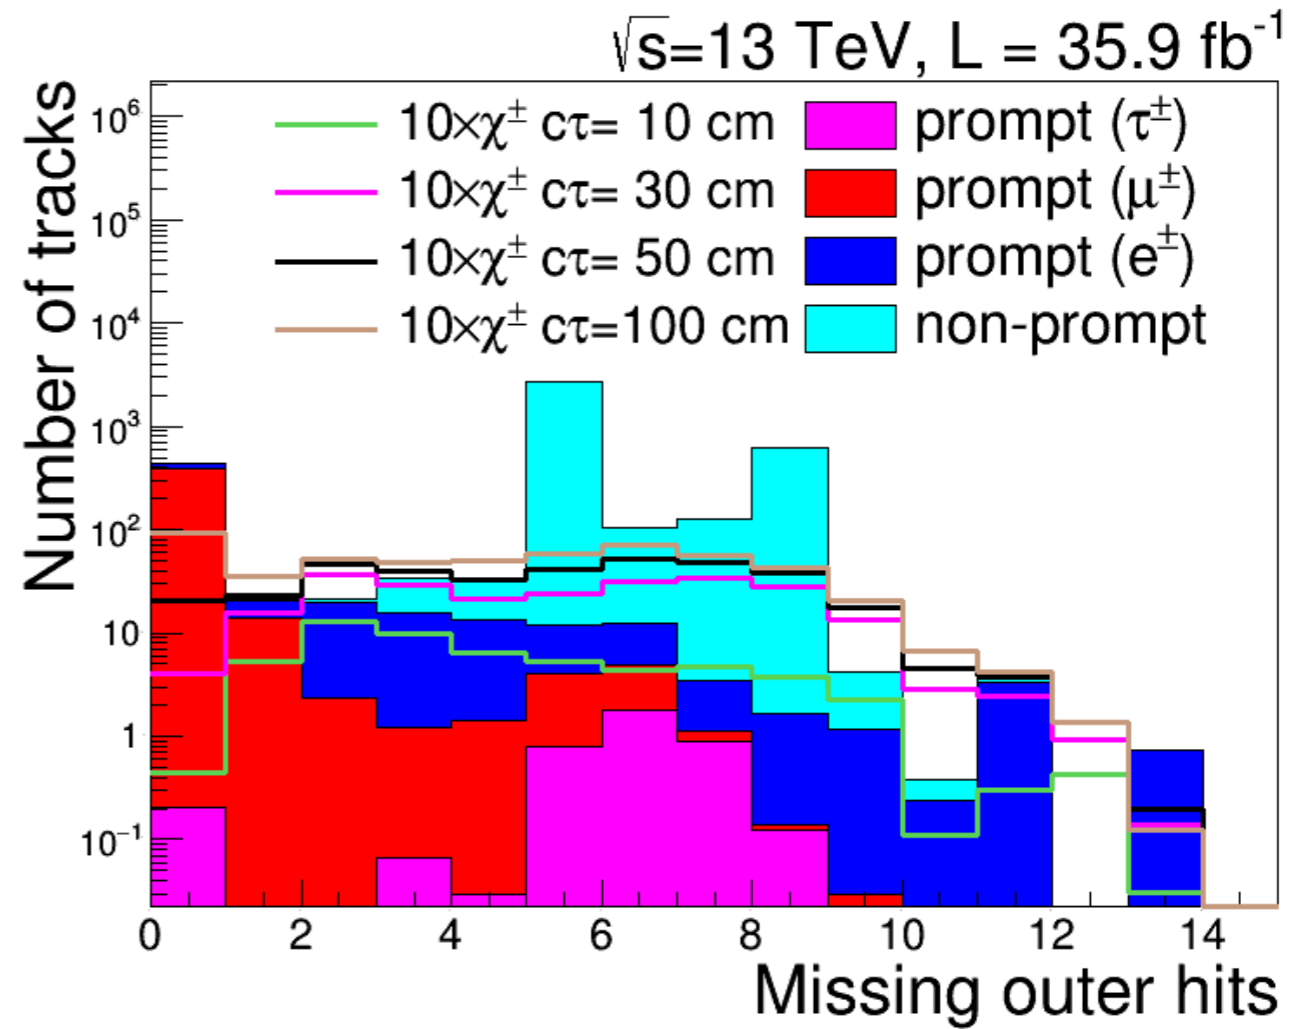

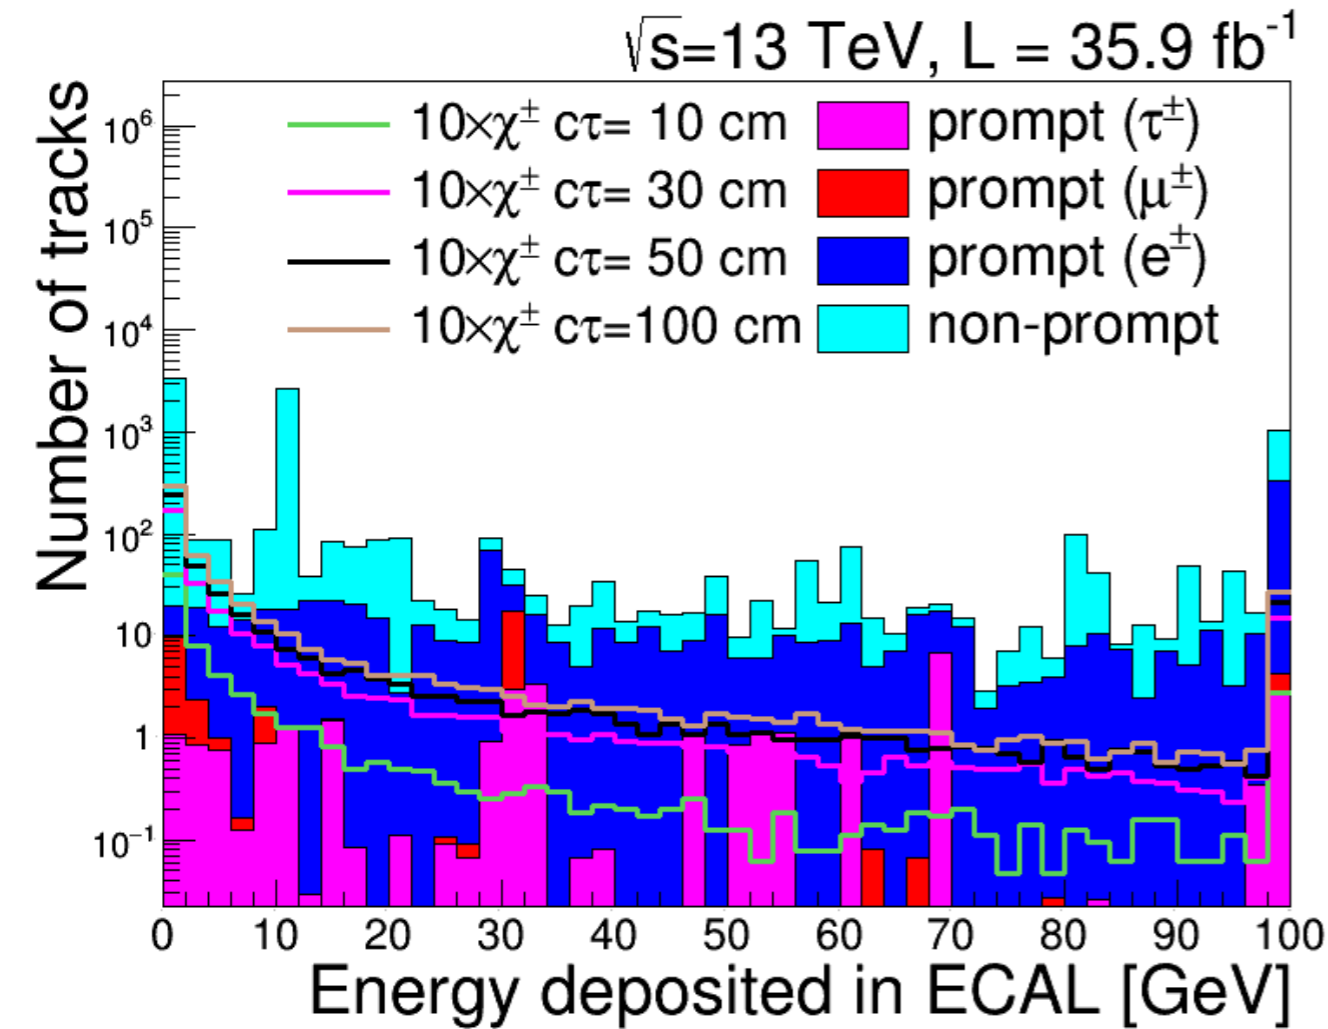

- Absolute (relative) isolation  $< 10$  GeV (0.01);  $dR < 0.01$

# Isolation from neutral particles

- Absolute (relative) isolation  $< 10$  GeV (0.01);  $dR < 0.05$

# Energy deposition and missing hits

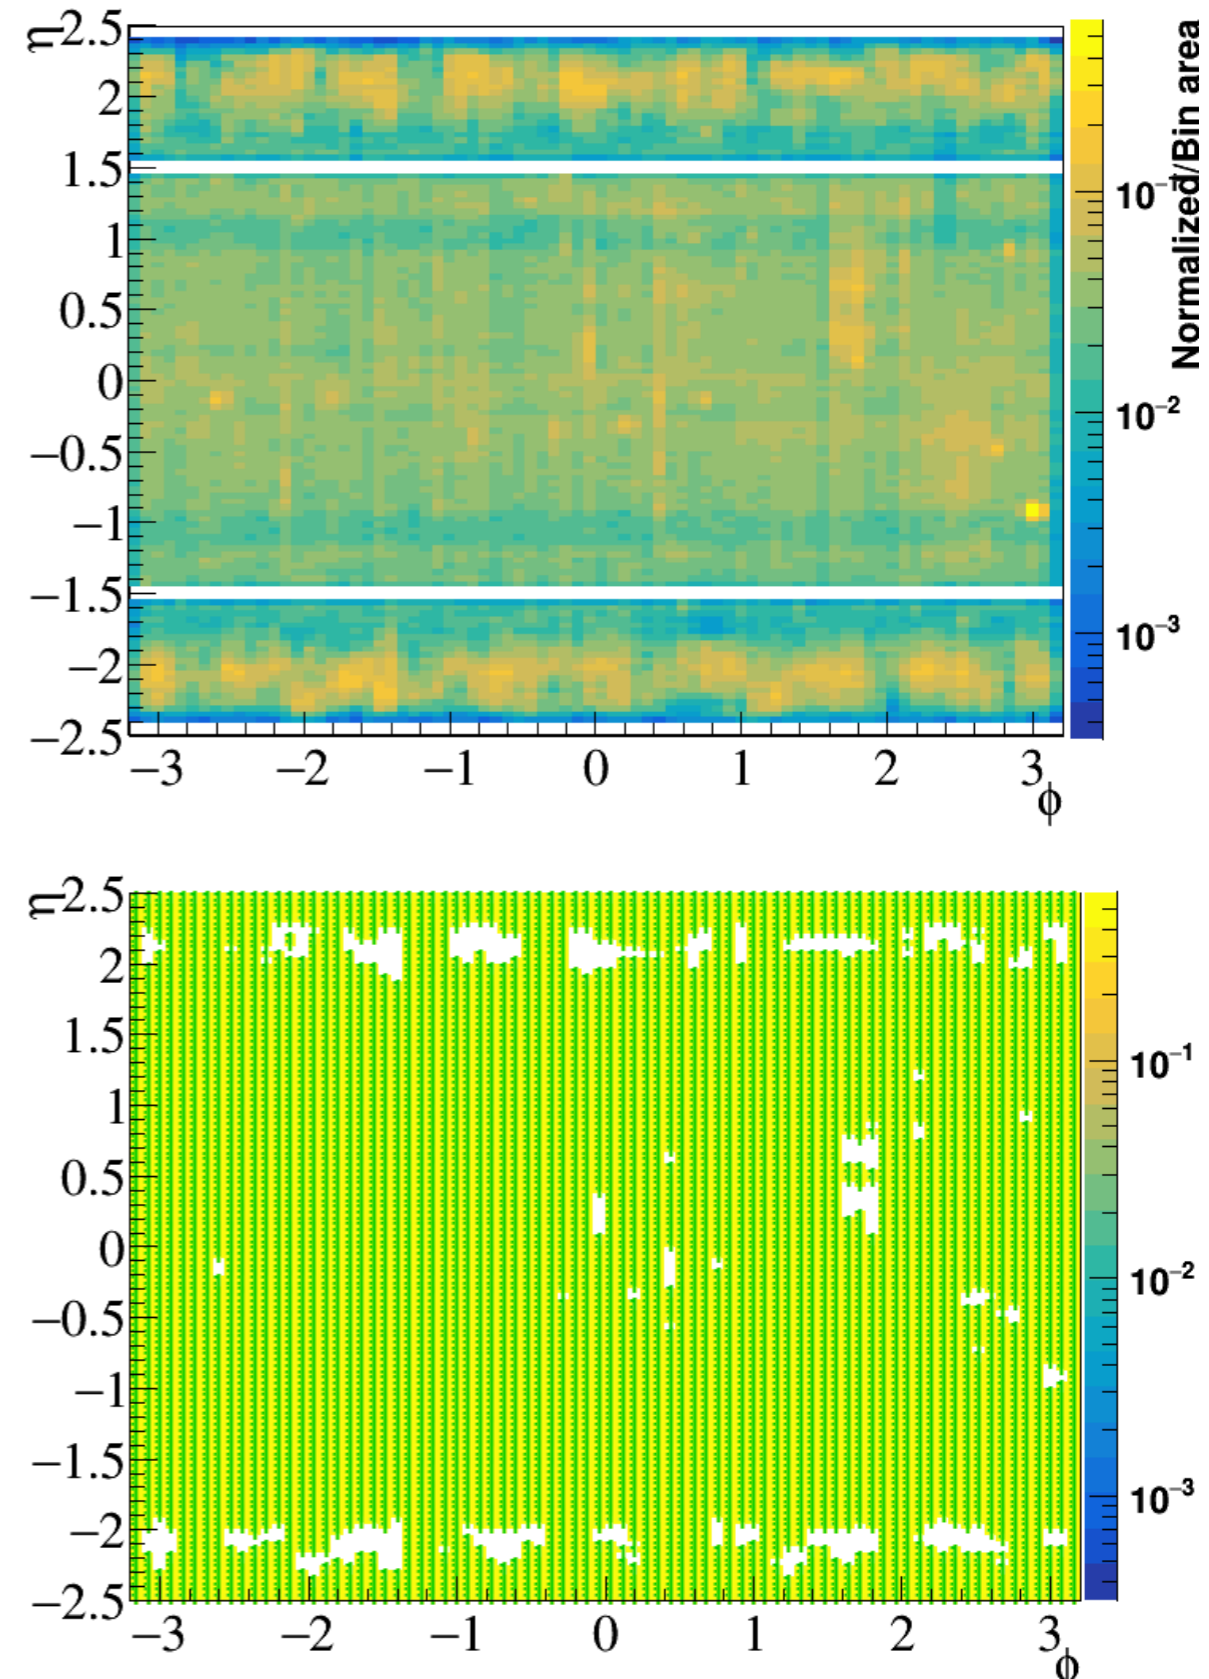

- Energy deposited in cone of  $dR = 0.5$ ;  $< 10$  GeV

- Missing outer hits  $> 1$

# Detector masks

- Distribution of disappearing tracks in eta-phi plane in data. (top)
- Distribution peaks at certain regions of detector with defects.
- Detector mask to veto the tracks pointing towards the region with defects; shown in white (bottom).
- Thus, the fiducial selection is added to the baseline track definition.

# Kappa calculation

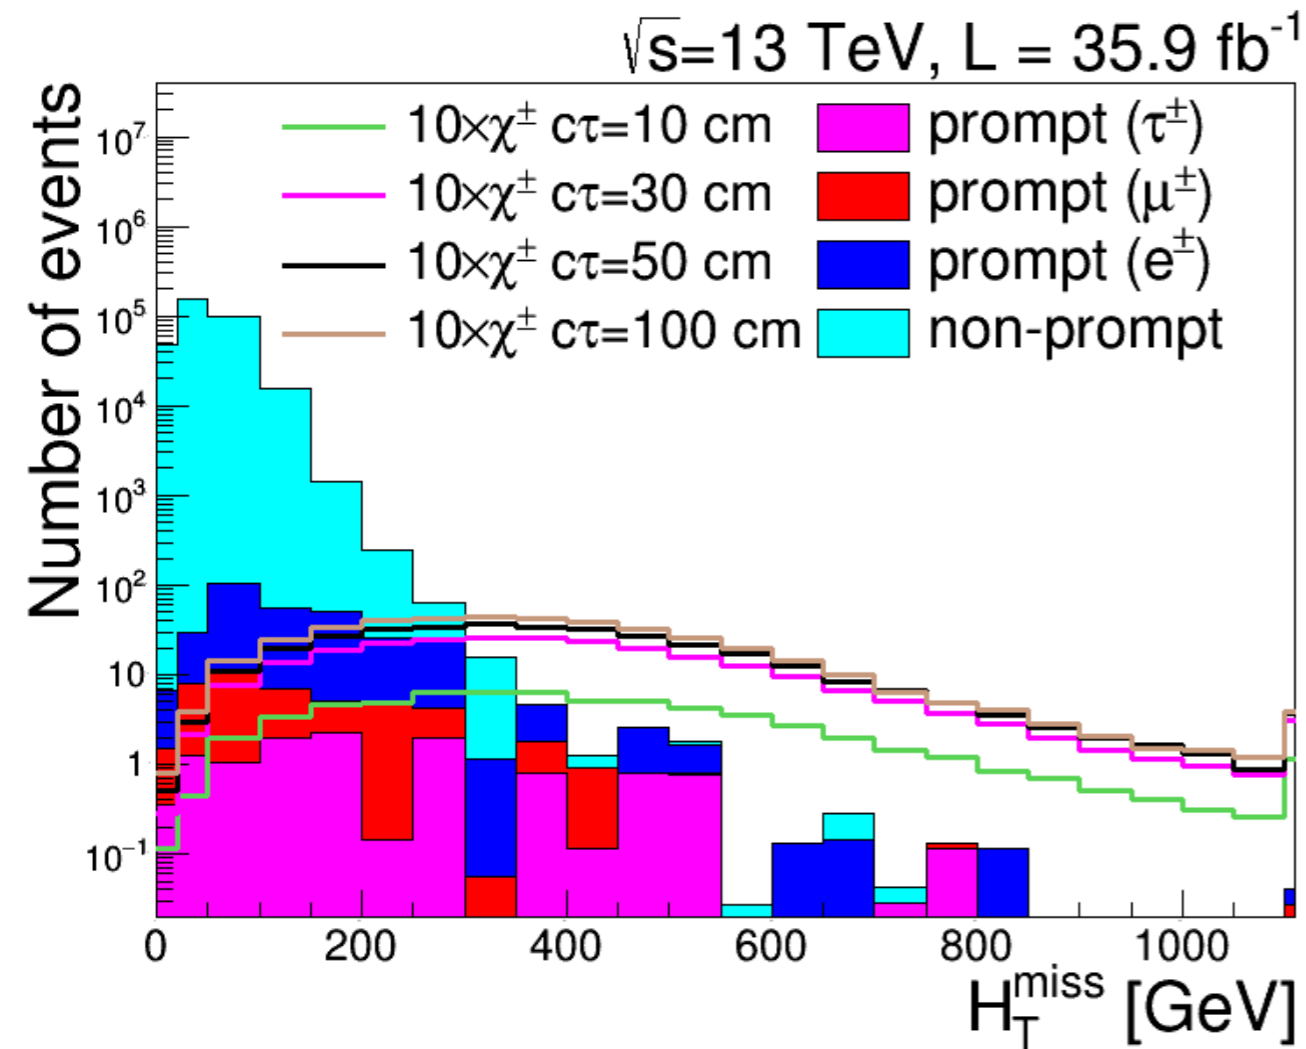

Tag is selected as:

- $p_T > 30 \text{ GeV}$  and  $0 < |\eta| < 2.4$
- pass tight lepton ID

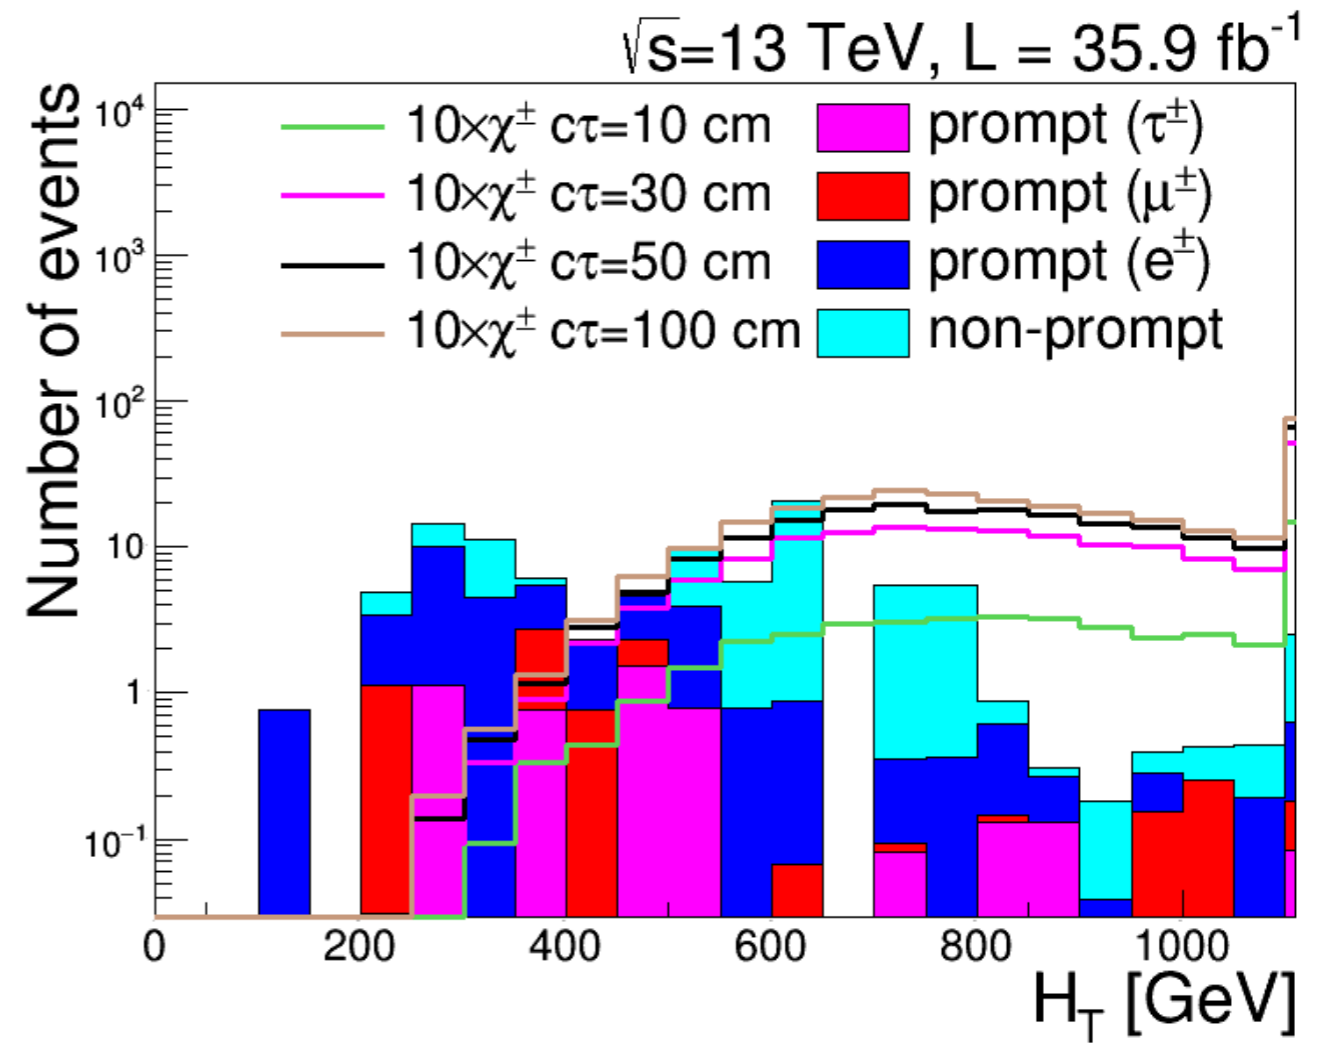

Probe is selected as:

- $p_T > 30 \text{ GeV}$
- $|\eta| < 1.442$  or  $1.566 < |\eta| < 2.4$
- $(\text{IM})_{\text{tag+probe}} - M_Z < 15 \text{ GeV}$
- $e_{\text{charge}}^{\text{tag}} + e_{\text{charge}}^{\text{probe}} = 0$

# Search variables

- $MHT > 250$  GeV,  $MHT = -\sum \vec{p}_T^{\text{jets}}$

- $H_T > 250$  GeV,  $H_T = \sum p_T^{\text{jets}}$

# Probe lepton smearing in simulation

- Resolution of reconstructed leptons is different from disappearing tracks;
- Smearing templates are reconstructed in bins of  $P_t$  and  $\eta$ . Using response defined as:

$$\text{response} = \log_{10} \left( \frac{p_T^{\text{reco}}}{p_T^{\text{true}}} \right)$$

- In simulation, the generator level  $P_t$  is considered as true  $P_t$ .
