GAUGE BOSONS
VECTOR BOSONS

SCALAR BOSONS

The Higgs boson

subject of my PhD
(and current) work

Force mediators

- The way how these particles *interact* is described by the **Standard Model**

The Higgs boson

- The Standard Model is built on gauge invariance principle
 - Does not allow massive gauge bosons → **W and Z masses?**
- **Solution** proposed by Peter Higgs & others (1964)
 - Add one scalar field to the theory, with a particular shape of the potential
 - The electroweak gauge symmetry is spontaneously broken
 - Mass terms for the W and Z bosons
 - Fermion masses from *ad-hoc* **Yukawa** terms
- Implication: there must be a **new particle, the Higgs boson**, with unknown mass!
- The search for it lasted *almost 50 years*

$$\begin{aligned}\mathcal{L} = & -\frac{1}{4} F_{\mu\nu} F^{\mu\nu} \\ & + i \bar{\psi} \not{D} \psi + h.c. \\ & + \bar{\chi}_i y_{ij} \chi_j \phi + h.c. \\ & + |D_\mu \phi|^2 - V(\phi)\end{aligned}$$

A Higgs-boson *factory*

How can we “see” it? First, we try to produce it

The Large Hadron Collider @ CERN

- Proton-proton collisions up to 13 TeV

Our eyes to see the Higgs

- The lifetime of the Higgs boson is extremely short: detect and measure the **decay products**
- **Largest and most complex detectors ever built**

A picture of the Higgs boson

After many of
such pictures

A peak in the
invariant mass
distribution

- It repeats many times, can't just be by chance
- The 5 sigma criterion

July 4th, 2012 @ CERN

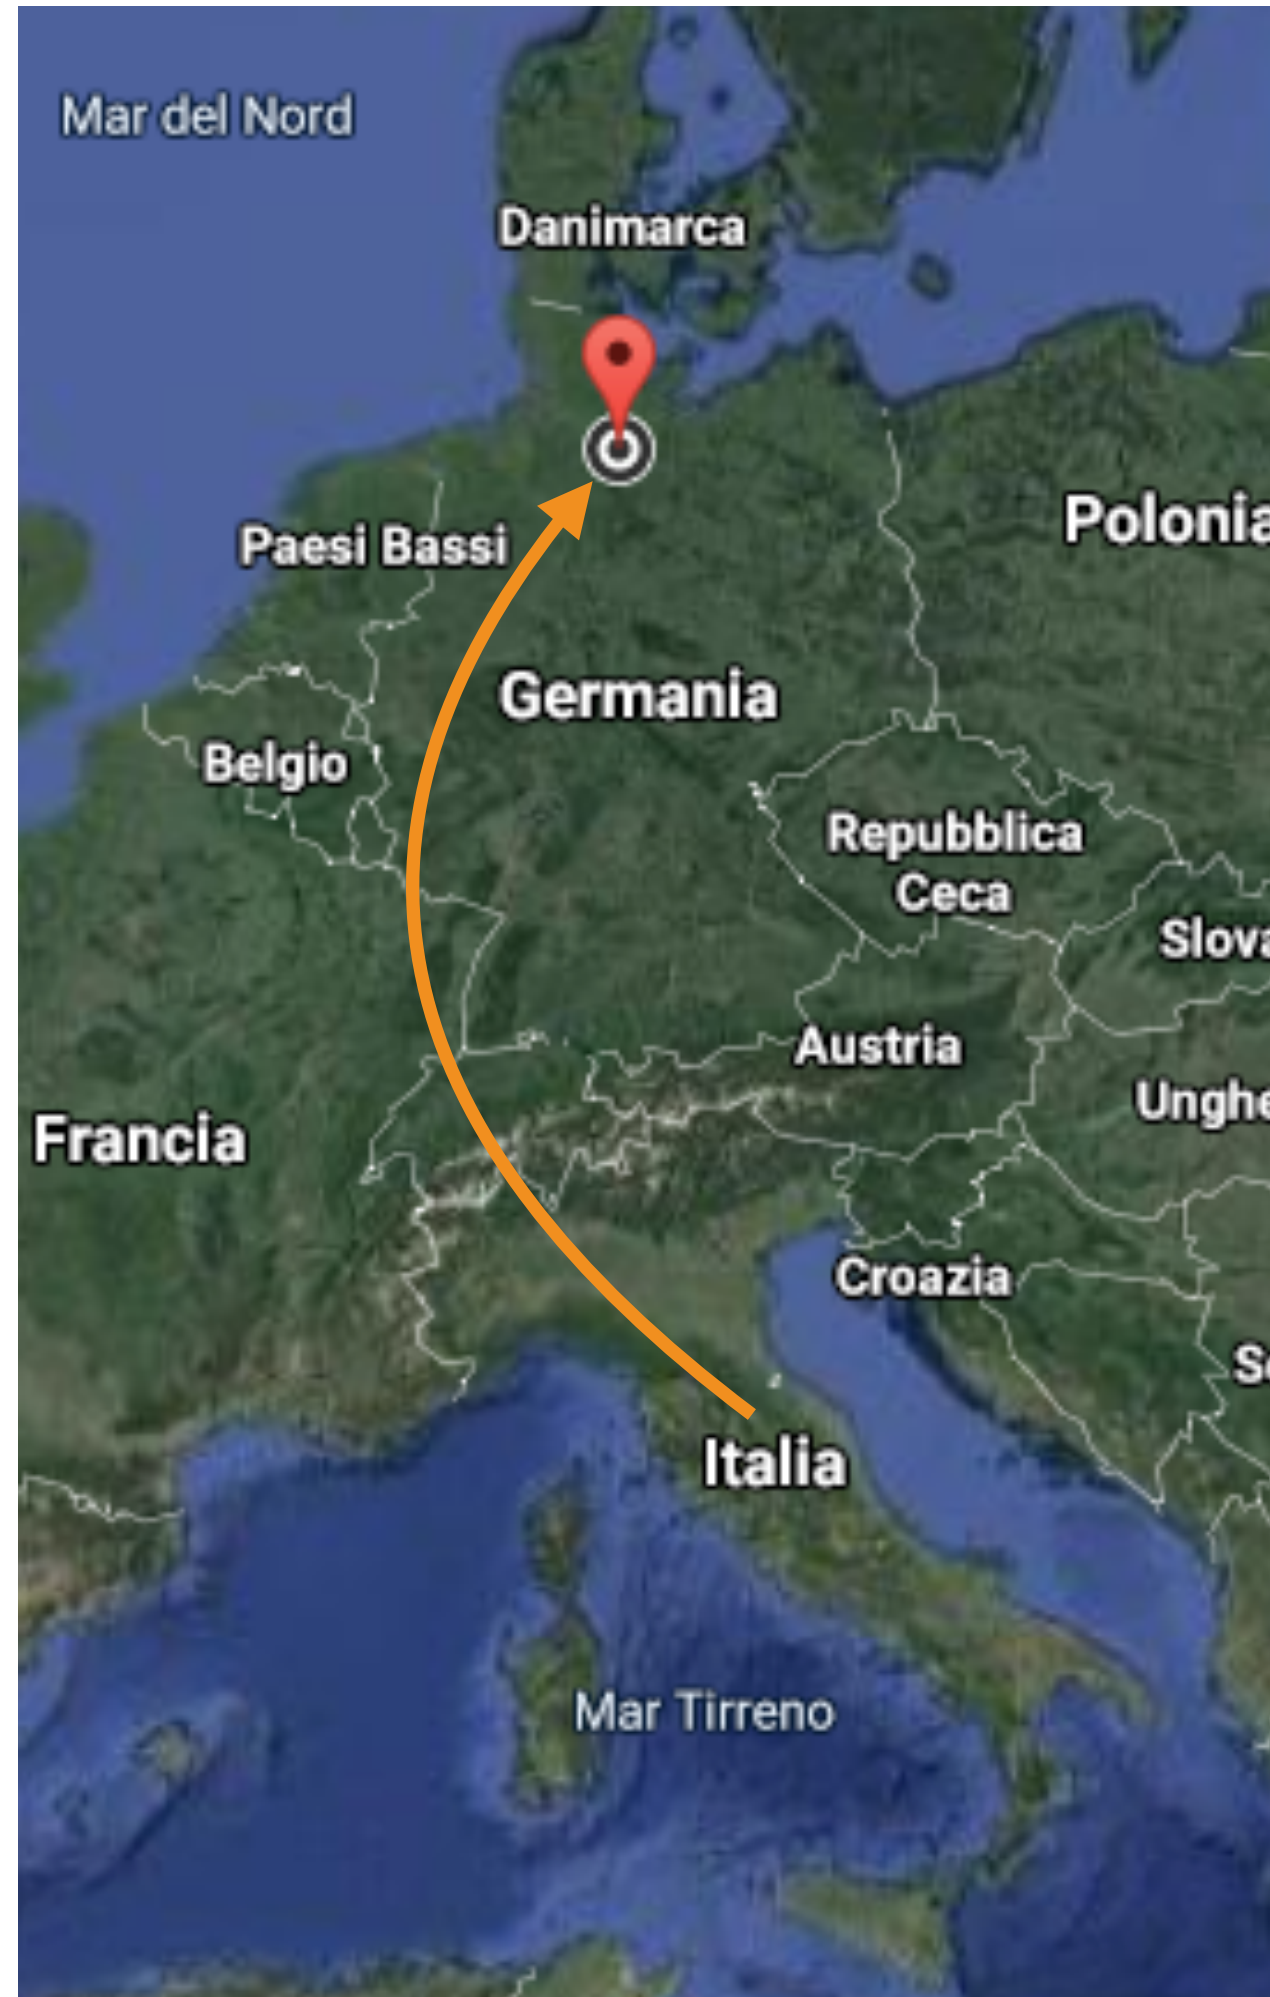

- **Discovery of the Higgs particle** announced on July 4th 2012 by ATLAS & CMS
- **Nobel prize** 2013 to Higgs and Englert

Denis Balibouse, Pool/AP

July 16th, 2012 @ DESY

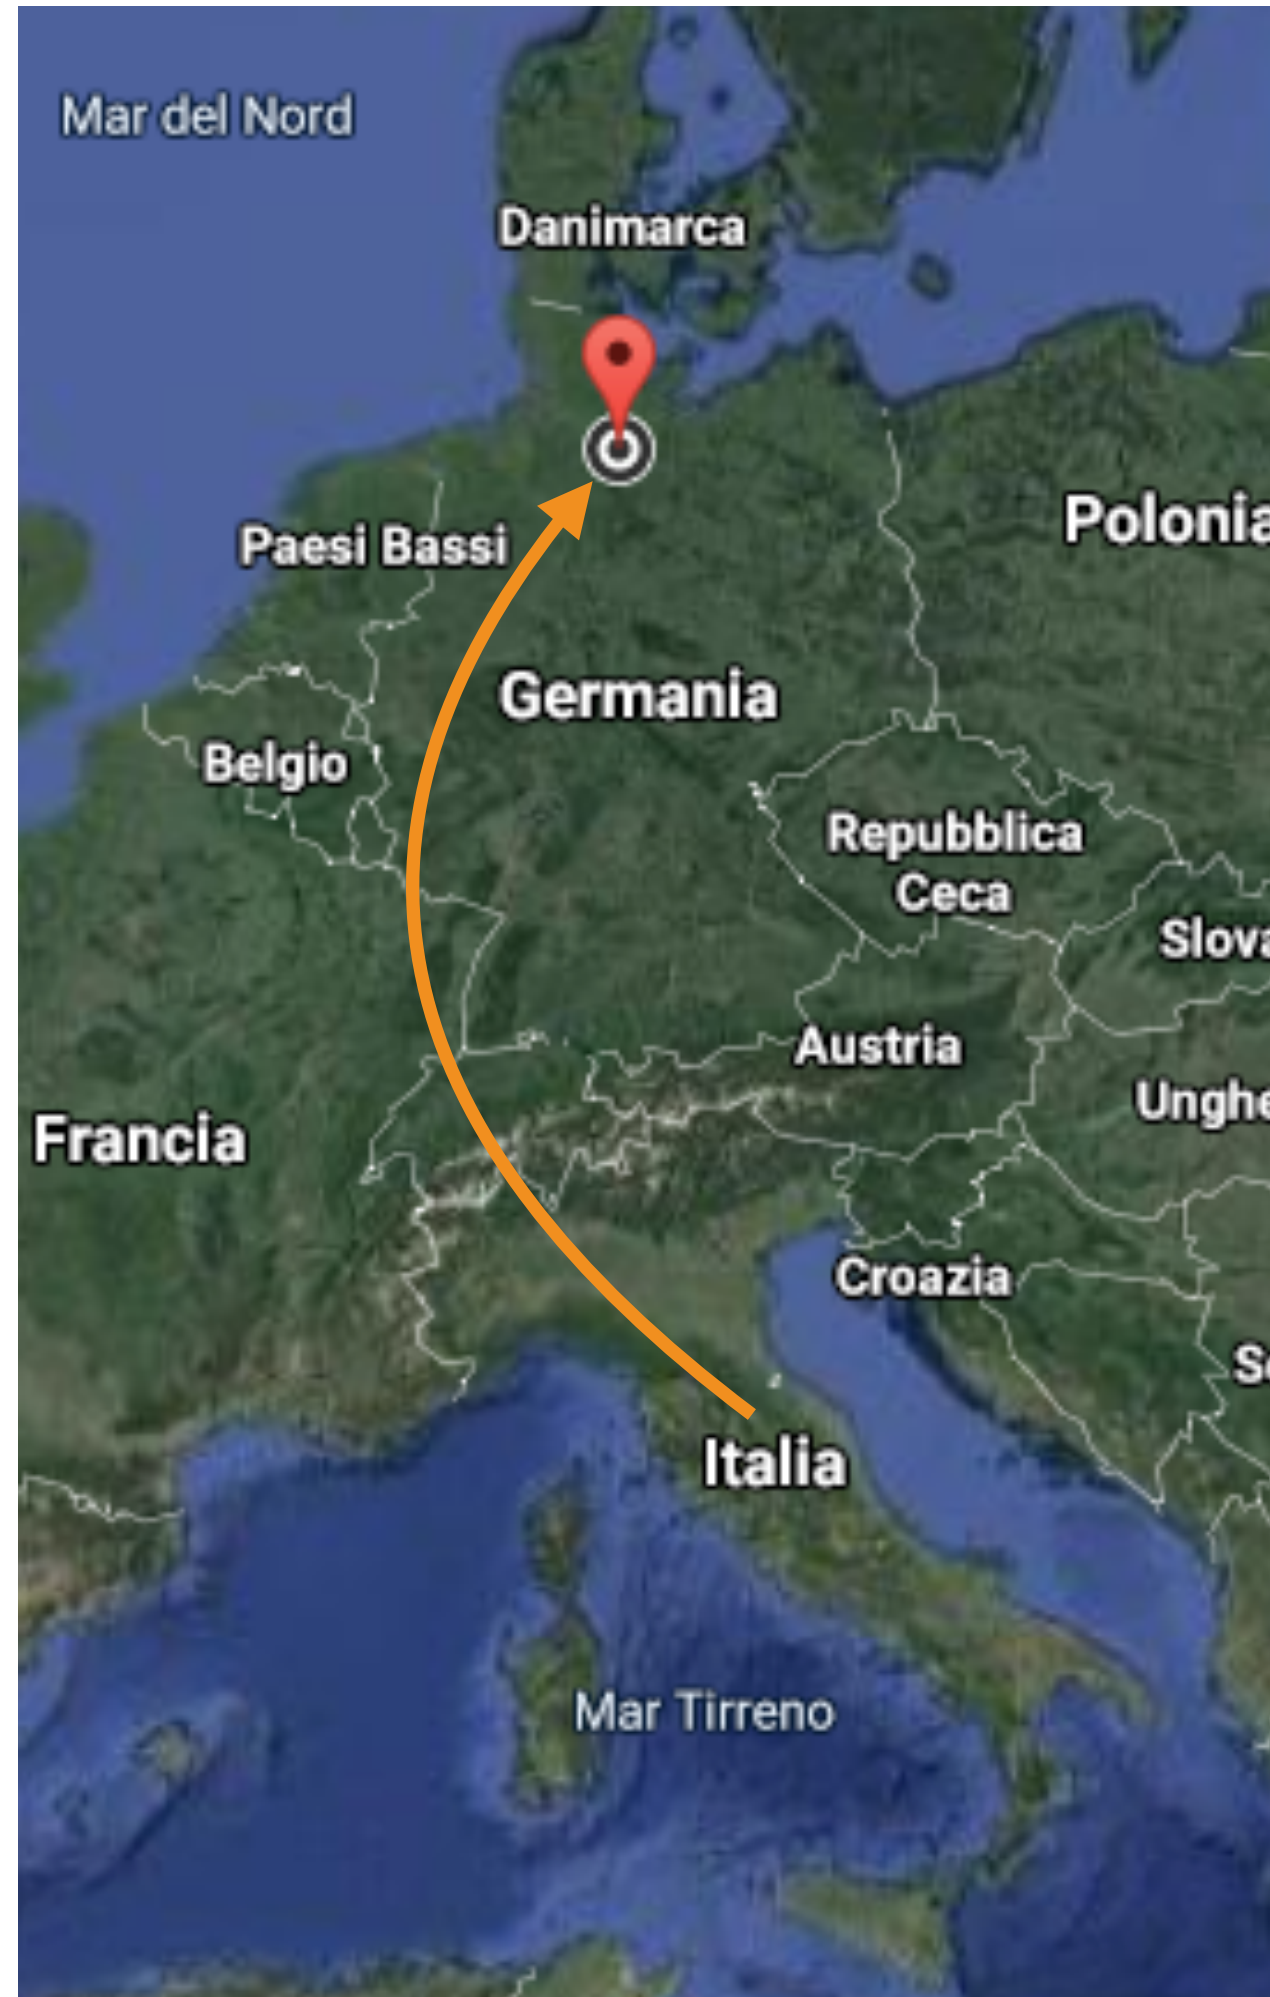

- I arrived as a **summer student**
- Got a project on the **CMS** experiment (!)
- First contact with real research

Group picture, Hamburg summer students 2012

A few years later...

- Back to DESY for my PhD in 2015
- **Higgs boson measurement in the decay to tau leptons (CMS)**
- Supervision of Prof. Elisabetta Gallo and Dr. Alexei Raspereza

Why tau leptons?

- The Higgs boson was discovered in decays to bosons (γ , Z)
- Direct measurement of coupling to fermions fundamental to probe its nature
- Higgs coupling proportional to mass

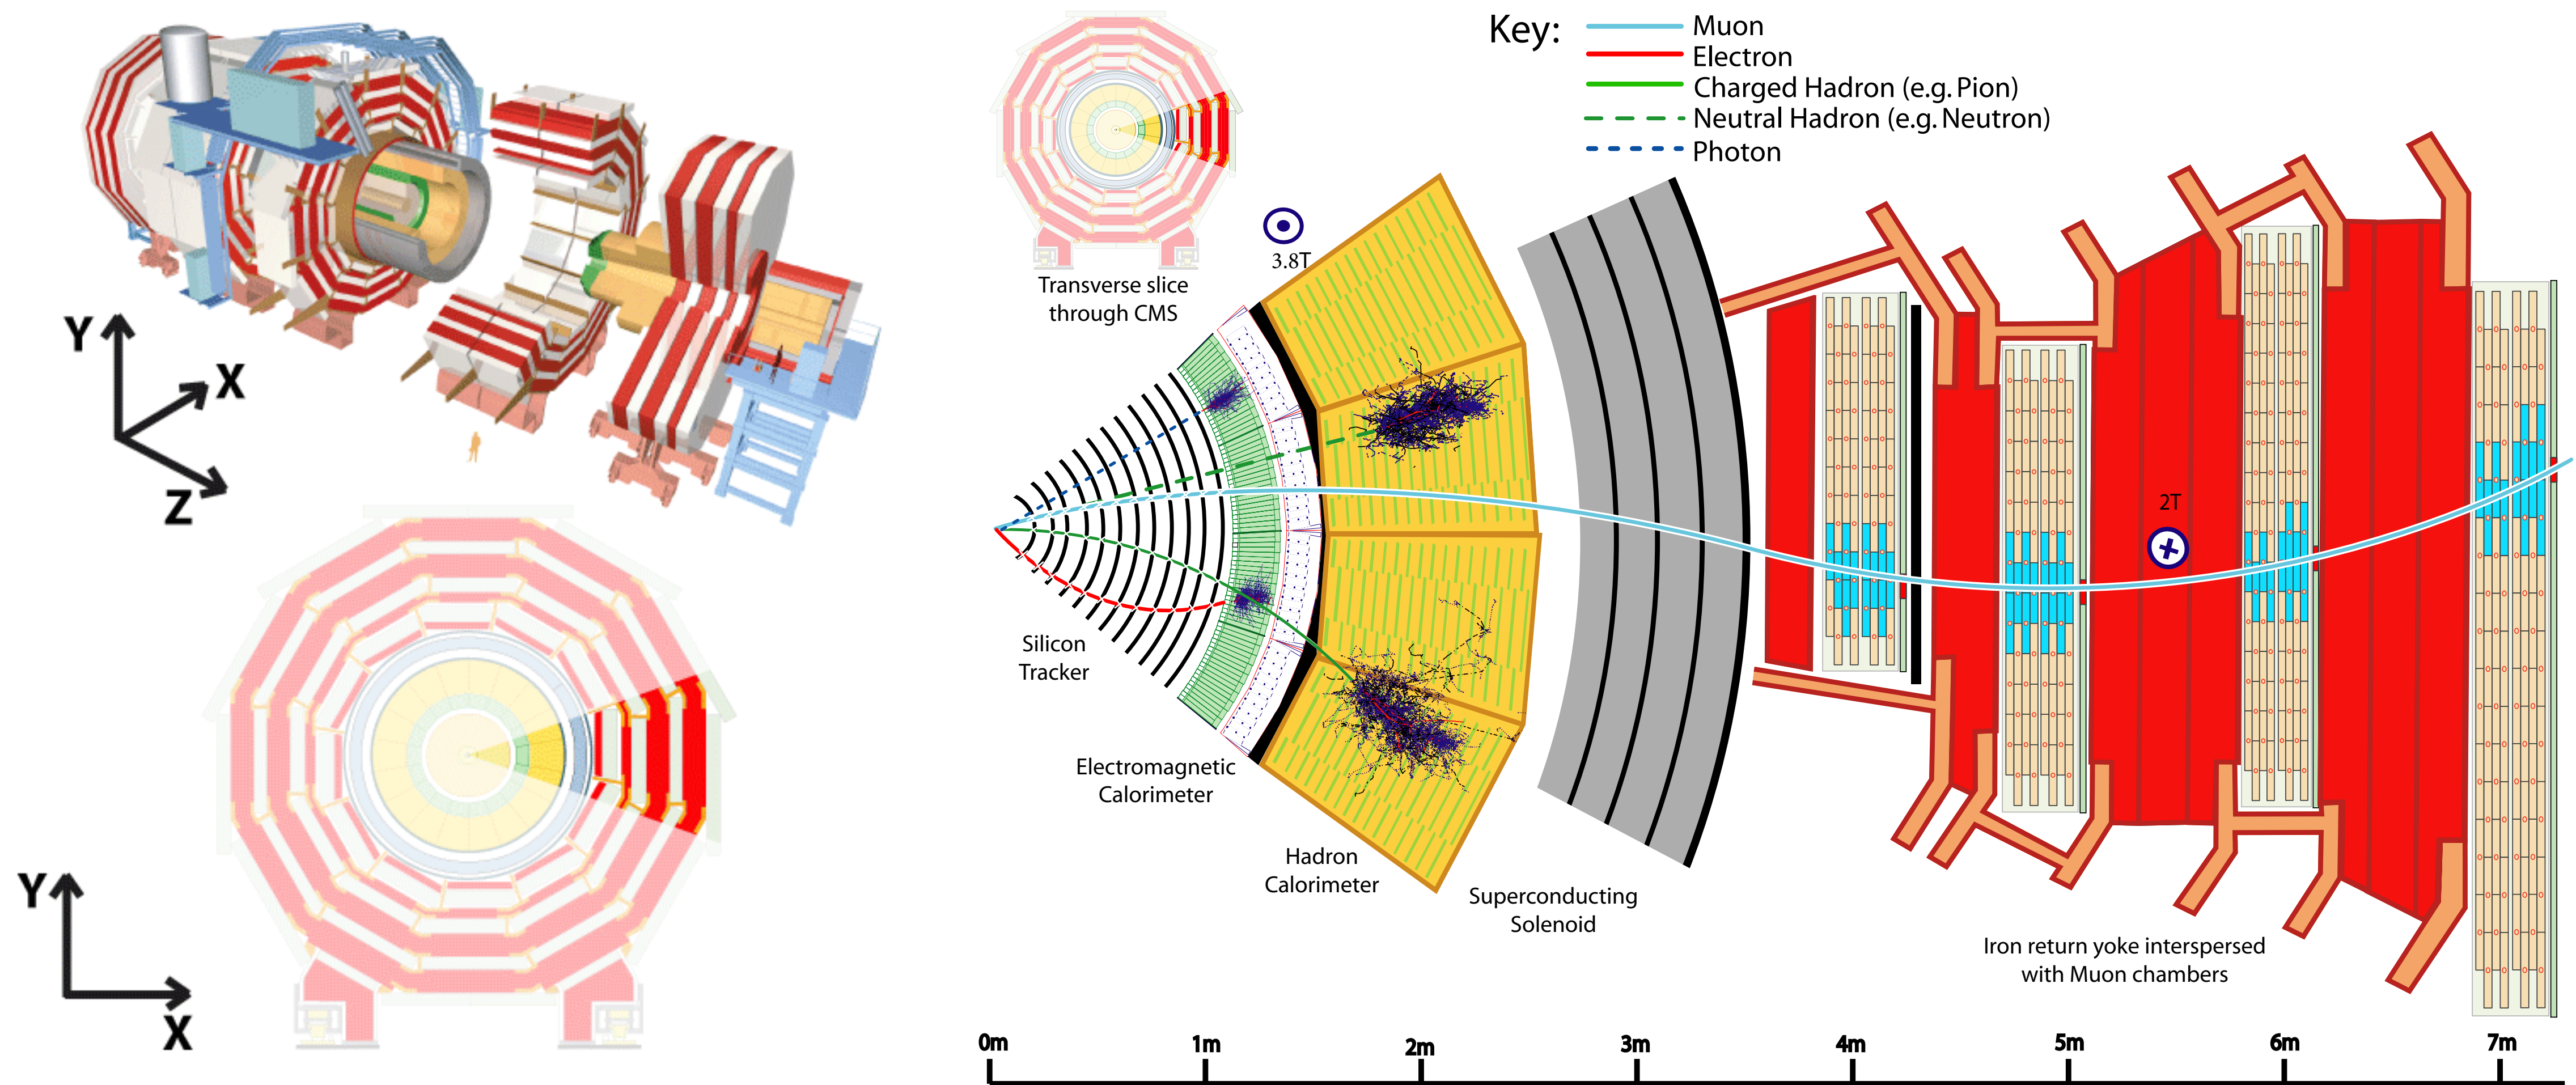

light \longrightarrow heavy

- Decay to tau tau is the **most important channel** despite its low **branching fraction**
 - Measurement of decays to bb suffers from large backgrounds

$$\mathcal{L} = -\frac{1}{4} F_{\mu\nu} F^{\mu\nu} + i\bar{\psi} \not{D} \psi + h.c. + \bar{\psi}_i Y_{ij} \psi_j \phi + h.c. + |D_\mu \phi|^2 - V(\phi)$$

Detecting and measuring particles

- Information from different subsystems exploited to identify and optimally reconstruct particles

How does a $H(\tau\tau)$ event look like?

- It depends on how the tau lepton decays
 - Charged hadrons (τ_{had}) + a neutrino
 - Muon or electron + neutrinos

How does a $H(\tau\tau)$ event look like?

- It depends on how the tau lepton decays
 - Charged hadrons (τ_{had}) + a neutrino
 - Muon or electron + neutrinos

What are the challenges?

1. Many collisions happen at the same time @ the LHC

What are the challenges?

2. A proton-proton collision is complex

What are the challenges?

3. The production of a Higgs boson is rare. The same particle content can be produced by other processes

Signal

1 event

Irreducible background

700 events

- Z and H bosons have different masses \longrightarrow precise measurement of the particle momentum is crucial

The CMS inner tracker

- The largest silicon tracker
- A very large magnetic field (3.8 T)
- Complemented by the muon spectrometer (increase leverage arm)

<https://cds.cern.ch/record/1225466>

Momentum resolution for tracks with $p_T \sim O(10 \text{ GeV})$ at subpercent level

<http://zitogiuseppe.com/cms/tracker2.gif>

Calibration is essential: tracker alignment

- Tracks are reconstructed fitting a set of hits on the tracker modules.
- Assuming wrong modules positions leads to bias in the reconstructed track

- Goal: measure position of single modules with a precision of a few micrometers
- My key contribution
 - **Study and execution of the first alignment of the new pixel detector (2017)**

The final results

- Despite a great detector and calibration, accurate data reconstruction, ...
- Not possible to reject all backgrounds
 - Accurate simulation, corrections derived from data
- Excess of events as expected by a Higgs boson
 - Observed significance of 4.9 sigma
 - Cross section compatible with the expectation

Combined with the 2012 result by CMS,

“First observation of $H(\tau\tau)$ decay by a single experiment”

Phys. Lett. B 779 (2018) 283

Standard Model

- Big open questions: dark matter, matter-antimatter asymmetry,

Gravitational lensing and dark-matter distribution (Hubble telescope)

Actually, this is just the beginning

- Does the Higgs boson interact with *unknown* particles?
- Is there only *one* Higgs boson?
- Does the “Standard Model” Higgs boson behave as predicted?
 - More *precise* measurement, new effects can be small

Higgs physics is moving discovery to precision era

It's now that things start becoming interesting!

DESY is playing a key role in Higgs physics

- Theory and both LHC experiments!

Thank you for your attention.
