

Status of low-energy data/MC disagreement

Bohdan Dudar

Deposited energy in the trackers is in disagreement

Particle deposited energy in Tr1

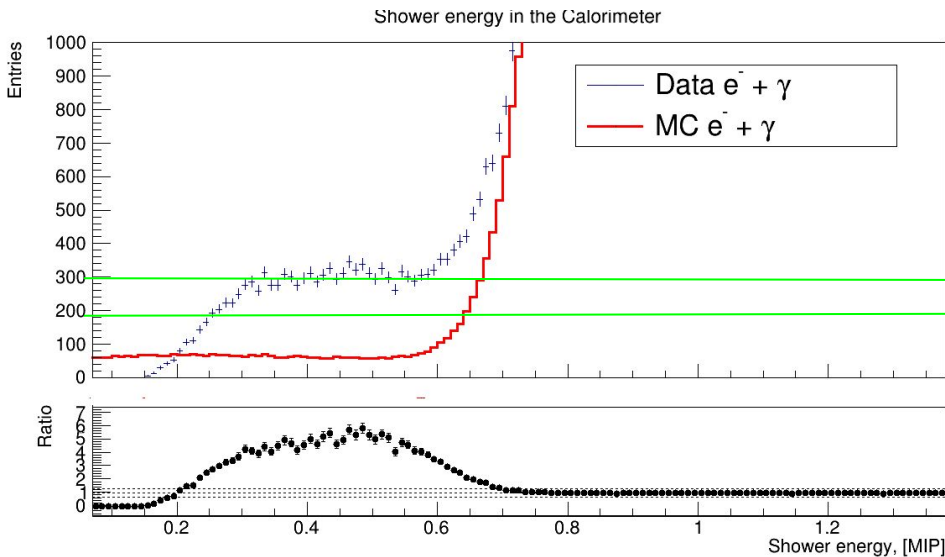

Renormalization without ZS hits doesn't help

Shower energy in the Calorimeter

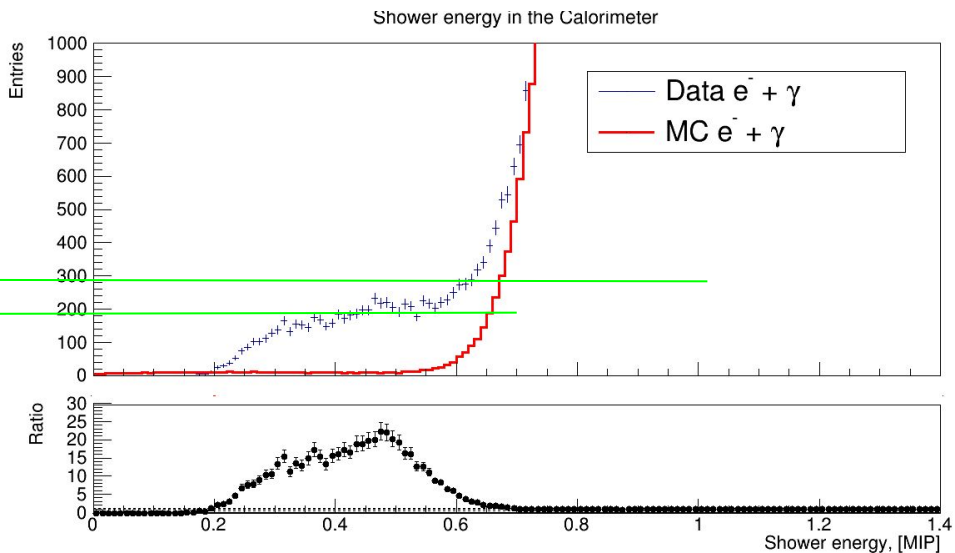

Plotting only 1st clusters vs all clusters

All clusters

Only 1st clusters

Particles of disagreement are the primary ones

All bad hits consist of only 1 pad

Tr1 cluster energy

This also confirms with their position

Position check of weird clusters in Tracker1

And their relative position to the shower

Position check of weird clusters in Tracker1

Conclusion

Low-energetic energy deposits:

- Are particles (correlation with a shower)
- Consist only of 1 pad (no signal sharing)
- Appear in events with only 1 cluster

Why doesn't it simulated by MC?

Checking correlation with NN_output

Signals spectrum passing NN output cut

After making data with $\text{NN_output} > 0.95$

NN > 0.5

Shower energy in the Calorimeter

NN > 0.95

Tr1 cluster energy

2 possibilities:

- 1) Energies of the hits are being wrongly reconstructed/measured by the electronics due to the large relative noise.
- 2) Simulation of full apvNoise instead of $0.6 * \text{apvNoise}$ will cover the region of disagreement, but then there will be much larger disagreement of the peak shape. Maybe it is solvable by reducing cut to $\text{NN_output} > 0.3$?

TODO:

Still have a lot to do.

I reinstalled old Scientific Linux 7 to the new CentOS 8 yesterday, so in process of installing Geant4 and root.

Also need to try copy files from a TAU cluster it got harder
