RESEARCH FOR GRAND CHALLENGES

August 4th 2020
CMS Top group presentation

Top quark physics at CMS-DESY

Nicolas Tonon for the CMS DESY group

STANDARD MODEL (SM)

2

- Describes elementary particles & interactions
 - ✓ Excellent data/theory agreement
 - ✓ 2012 : Higgs Boson discovery (predicted in 1964 !)

STANDARD MODEL (SM)

3

- Describes elementary particles & interactions
 - ✓ Excellent data/theory agreement
 - ✓ 2012 : Higgs Boson discovery (predicted in 1964 !)

? Several **missing pieces** :

- ✗ Dark matter, neutrino masses, ...
- ✗ Gravity not included, ...

- Many « Beyond Standard Model » (**BSM**) scenarios postulate explanations (new particles, mechanisms, etc.)

- New physics accessible through

THE TOP QUARK IS SPECIAL

4

- Top quark (1995, Tevatron) has several **unique features** :

- Heaviest known fundamental particle
- Only quark decaying before forming bound state (hadrons)
- Signature decay : $t \rightarrow W b$

Leptonic decay to e or μ ($\sim 20\%$)
offers **best signal/background** ratio

173 GeV

Gold atom
183 GeV

THE TOP QUARK IS SPECIAL

5

- Top quark (1995, Tevatron) has several unique features :

- Heaviest known fundamental particle
- Only quark decaying before forming bound state (hadrons)
- Signature decay : $t \rightarrow W b$

173 GeV

Gold atom
184 GeV

Leptonic decay to e or μ ($\sim 20\%$)
offers **best signal/background** ratio

$t\bar{t}$ pair production (QCD) : dominant at LHC, $\sigma \sim 800$ pb

Single top (electroweak) : observed in 2009, $\sigma \sim 280$ pb

$\sim 130M$ $t\bar{t}$ pairs

 Run 2
(2015–2018)
 $\sim 50M$ single top quarks

Extremely **rich phenomenology**, probes profoundly self-consistency of Standard Model

PHYSICS EXAMPLE

Search for top-Z associated production (tZq)

- Single top quark process, recently observed at LHC for the first time
- **Directly** sensitive to top-Z coupling
- Many BSM scenarios predict deviations in cross section & kinematics

7

A VERY TINY SIGNAL...

8

(Of total single-top cross-section)

- Target events with **3 leptons** in final state (clear signature, best signal/bkg ratio)

Light jet emitted in forward region (parallel to beams)

Neutrino not detected (missing energy)

b-jet *tagged* using dedicated algorithm

- Main steps of a typical search at the LHC :

*Most of the analyst's work
(understand simulation,
estimate backgrounds, etc.)*

My favourite part !

- Rare signal can't be separated efficiently from immense backgrounds using just few observables

Multi-variate analysis → Check many observables to decide whether event is more **signal-** or **background-like**

- This process must be automated → **Machine-Learning** techniques (e.g. neural networks)
 - Easy to implement but... requires lots of optimization (simul.) and validation (simul. + data) !

(good separation, but sub-optimal)

Optimal variable from Machine-Learning

- Estimate the 'signal' contribution by fitting the simulation to the data

First observation of this rare process

Observed significance : **8.2 σ** (7.7 σ expected)

« STATISTICAL DISCOVERY » ?

12

Example : search for the Higgs boson

Number of collisions

5 fb⁻¹ of data, 7 TeV

36 fb⁻¹ of data, 13 TeV

Mass
(4-leptons)

Is the excess of data « statistically significant »... ?

Prediction of null hypothesis
= SM without Higgs

For a given mass range (bin) :

- If dataset is large enough, # of observed events N_{null} predicted by null hypothesis H_0 approximately follows a normal distribution

Prediction of null hypothesis
= SM without Higgs

Observation

For a given mass range (bin) :

- If dataset is large enough, # of observed events N_{null} predicted by null hypothesis H_0 approximately follows a normal distribution

- Significance: $\mathcal{S} = (N_{obs} - N_{null})/\sigma$

- P-value: $p = \int_{N_{obs}}^{+\infty} H_0 \cdot dx$

$\mathcal{S} = 3 \sigma \rightarrow \ll \text{EVIDENCE} \gg$

$\mathcal{S} = 5 \sigma \rightarrow \ll \text{OBSERVATION} \gg$

N_{null}

EVENTS

- Several top quark couplings (to Z , γ , H) are still quite **poorly known**
 - Many BSM extensions predict sizeable **deviations**
- Effective Field Theory** (EFT) provides framework to interpret potential deviations from SM predictions
 - Assume new physics is characterized by energy scale $\Lambda \gg E_{LHC}$
 - Expand SM Lagrangian with higher-order operators
 - Model-independent $\rightarrow$ Can **re-interpret results** within different models

$$\mathcal{L}_{eff} = \mathcal{L}_{SM} + \sum_i \sum_{d>4} \frac{\overset{\text{Strength}}{\underbrace{C_i^d}_{\text{Higher-order operators}}}}{\Lambda^{d-4}} \mathcal{O}_i^d$$

- Example: Fermi theory of weak interaction ($E \ll m_Z, m_W$)

The actual **W boson** ... approximated as ... **an effective interaction**

BACKUP

↔ 22m long
↗ 15m diameter

- General-purpose detector, broad physics programme
- Many specialized sub-detectors

- Combine informations from all sub-detectors

→ Identify nature of created particles

→ Reconstruct full picture of the event

$H \rightarrow \gamma\gamma$

- 27 km circonference
- 10^9 **proton** collisions/second
→ Can study rare particles
- **Highest energy** ever achieved
 - 13 Tera-electronvolts (TeV)
 - $E = M.c^2$
