- ▶ Beam lifetime: defined via the **current decay rate**

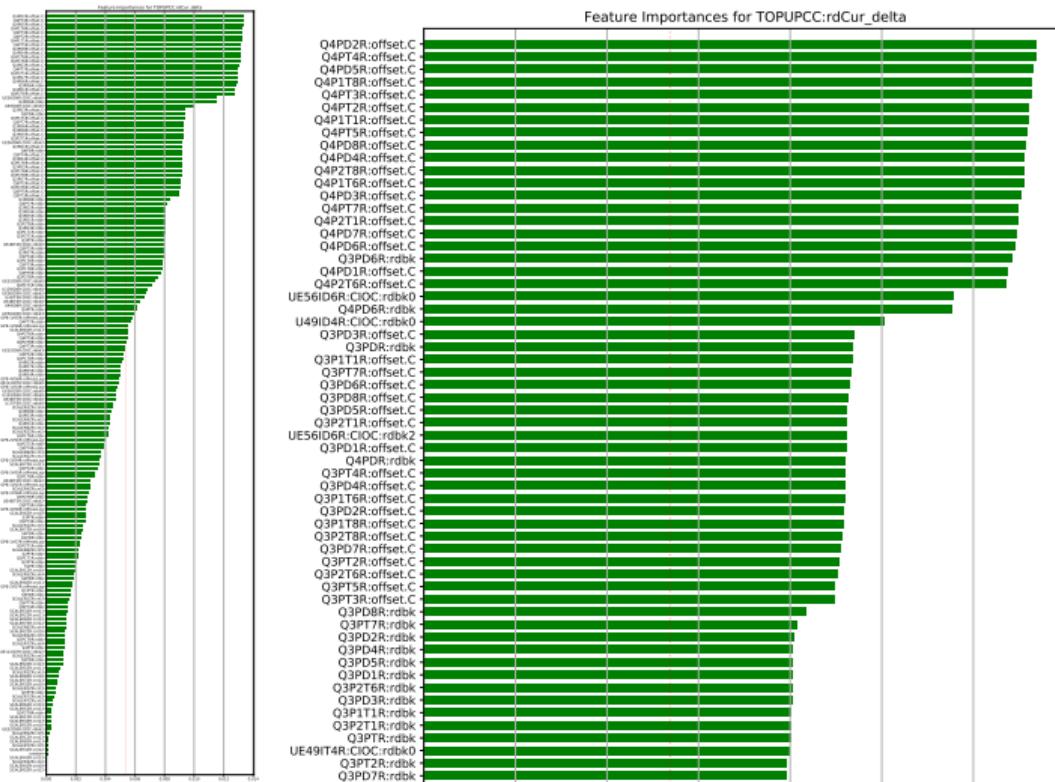

$$\frac{1}{\tau} = -\frac{\dot{I}}{I}$$

- ▶ EPICS Variable can't be used - very delayed
- ▶ First approach: exact calculation from measurements - unstable due to measurement errors

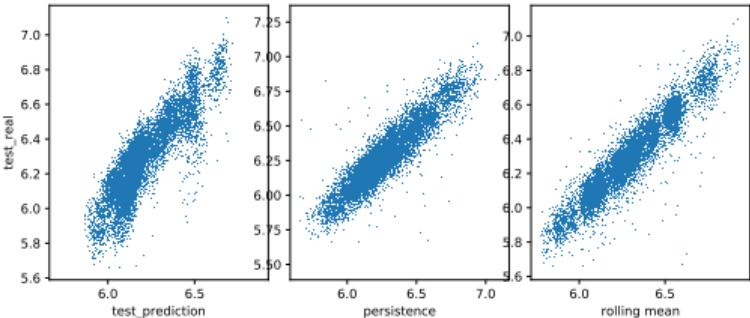

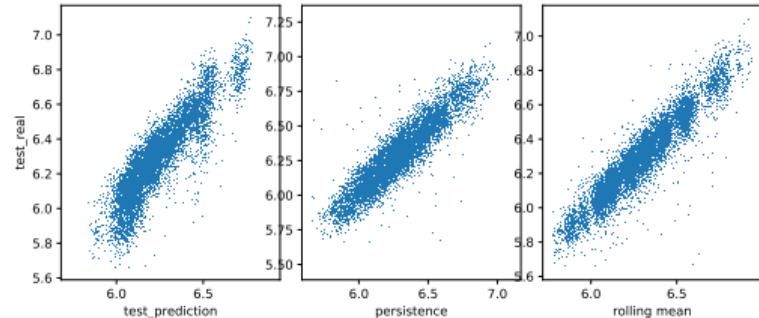

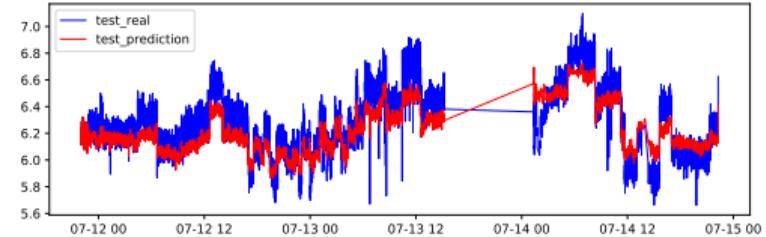

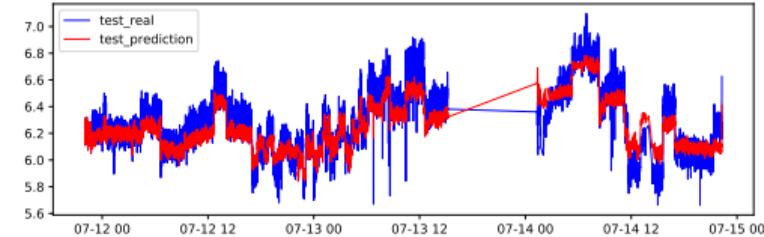

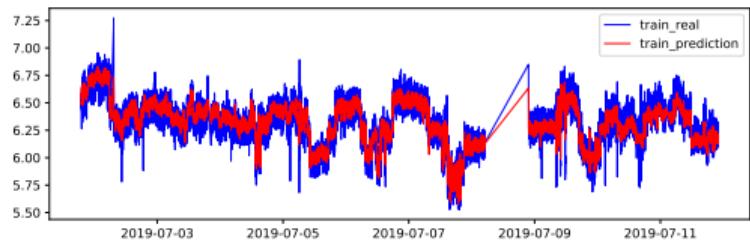

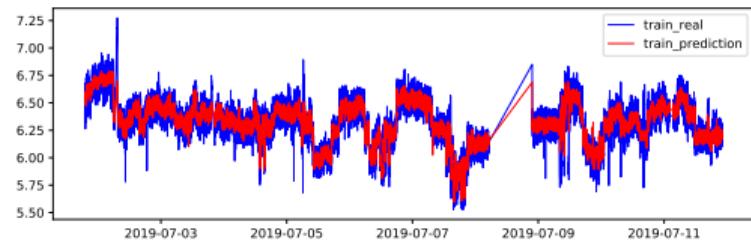

$$\frac{1}{\tau} = -\frac{\ln(I_t) - \ln(I_{t_0})}{t - t_0}$$

- ▶ Final approach: **piecewise linear regression** with k previous measurements (experiments with $k = 20$)

$$\frac{1}{\tau} \approx -\frac{1}{I_t} \frac{\sum_{i=0}^k (I_{t-i} - I_{t_0})(t - i - t_0)}{\sum_{i=0}^k (t - i - t_0)^2}$$

- ▶ **185 input variables:** undulator gaps and shifts (21), quadrupole (58) and sextupole (7) currents, quadrupole offsets (38), local beam loss measurements (49)...
- ▶ Evenly distributed feature importances - **quadrupoles** (offsets) and **undulator** gaps stand out.

We can define the injection efficiency as the **fraction of current increase** generated in the storage ring by the charge accelerated in the booster.

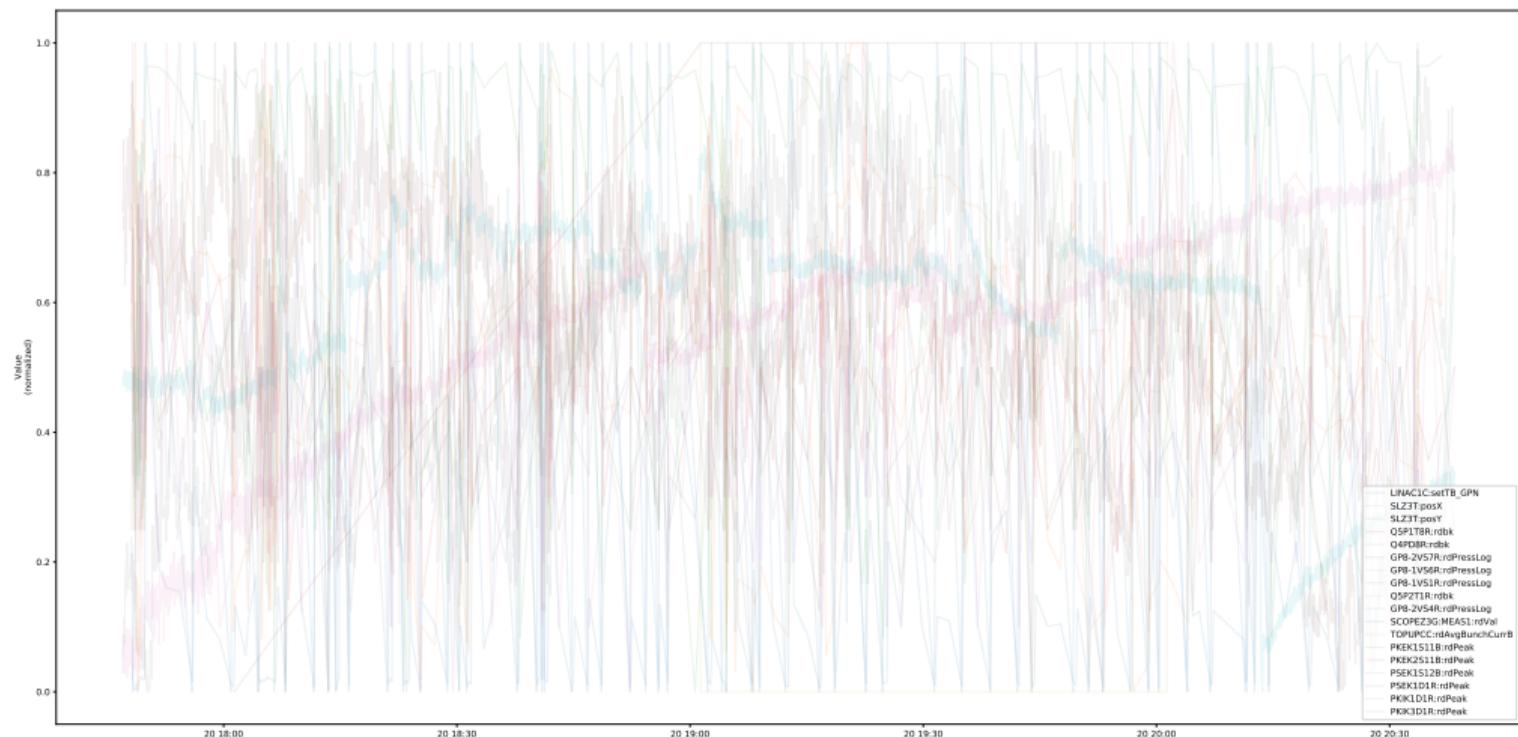

Injection efficiency is known to be affected by temperature and nowadays needs **manual tuning** → suitable for **RL-based optimization**

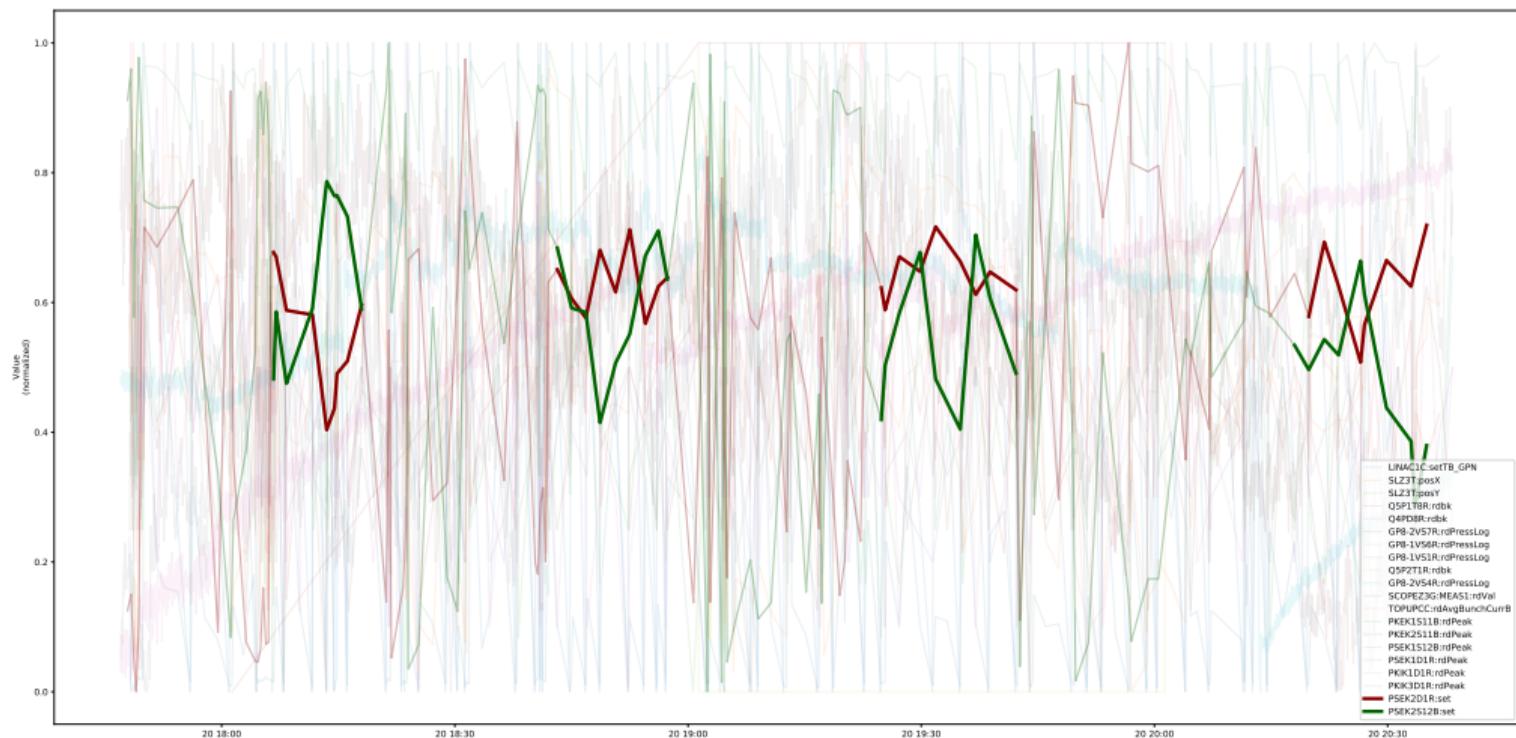

- ▶ Action variables:
 - ▶ **Deflection angle into the storage ring**, generated by the 2nd septum.
 - ▶ **Deflection angle into the booster**, generated by the 2nd septum.
- ▶ State variables (19):
 - ▶ Number of **bunches** generated by the LINAC (1, 3 or 5).
 - ▶ Injection angle **mismatch**, measured by the beam position in the transfer line (x,y).
 - ▶ **Current** measured during the booster acceleration phase.
 - ▶ Measured **loss rate after extraction** from the booster.
 - ▶ Power supply currents into **quadrupoles** (3 variables).
 - ▶ Collisions with rest gas particles and vacuum pressures (4 variables).
 - ▶ Peak intensity of the remaining ring and booster septa and kickers (6 variables).
- ▶ Reward: **injection efficiency** of the last shot.

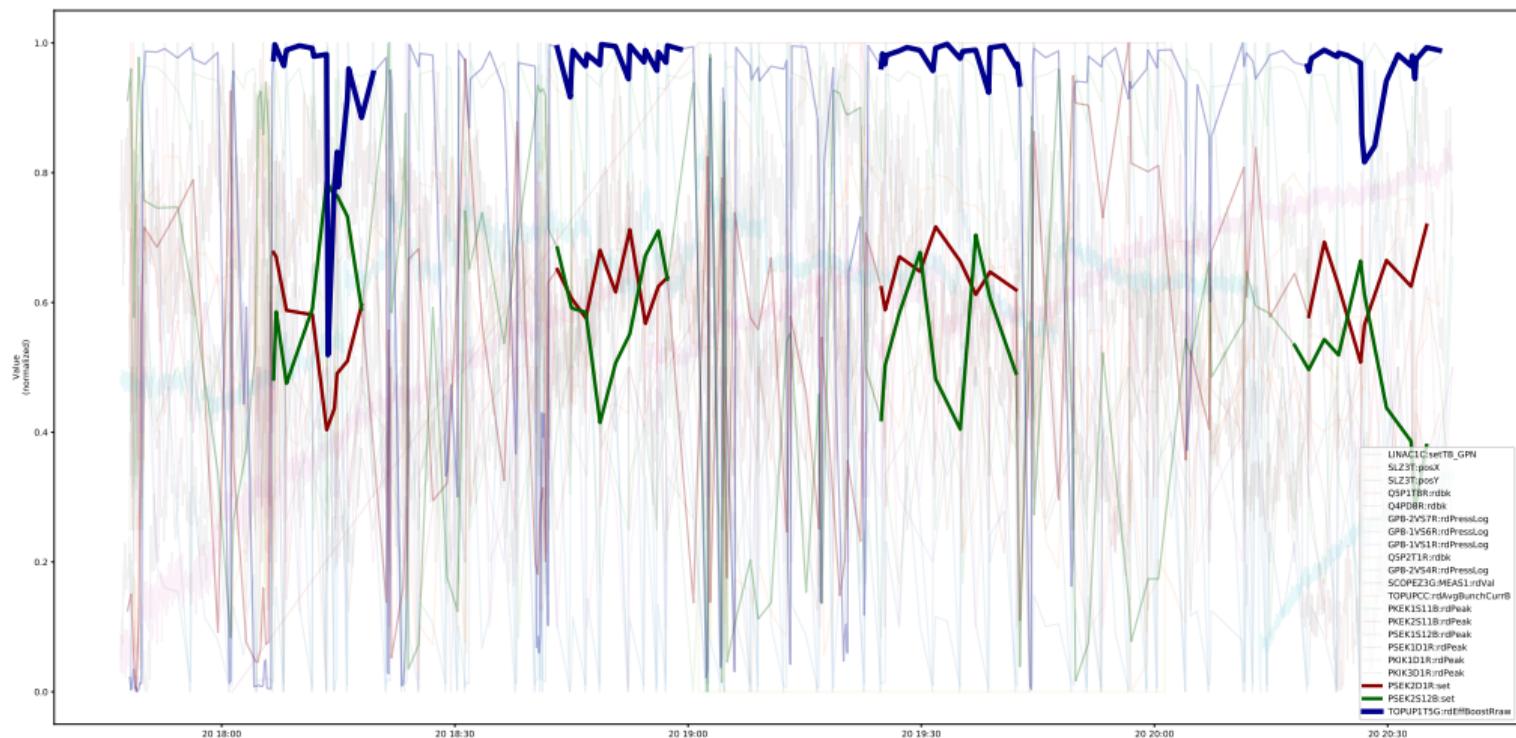

Observed states:

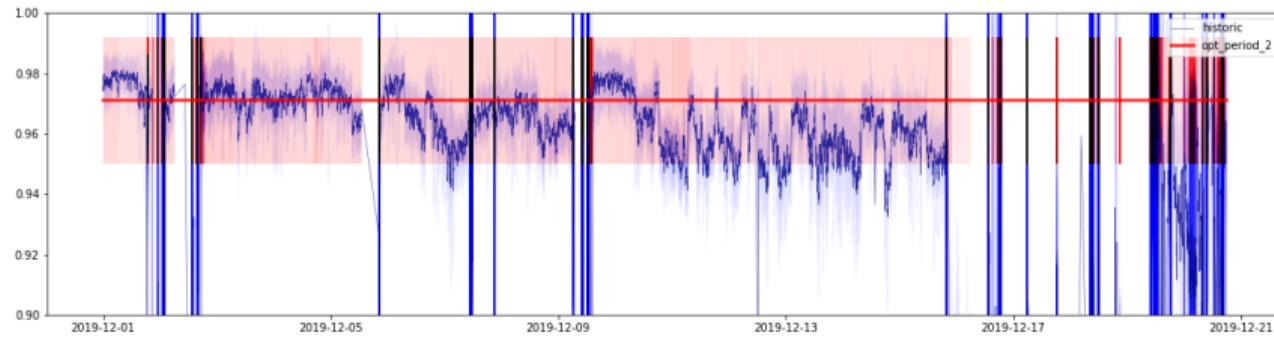

Observed states + actions:

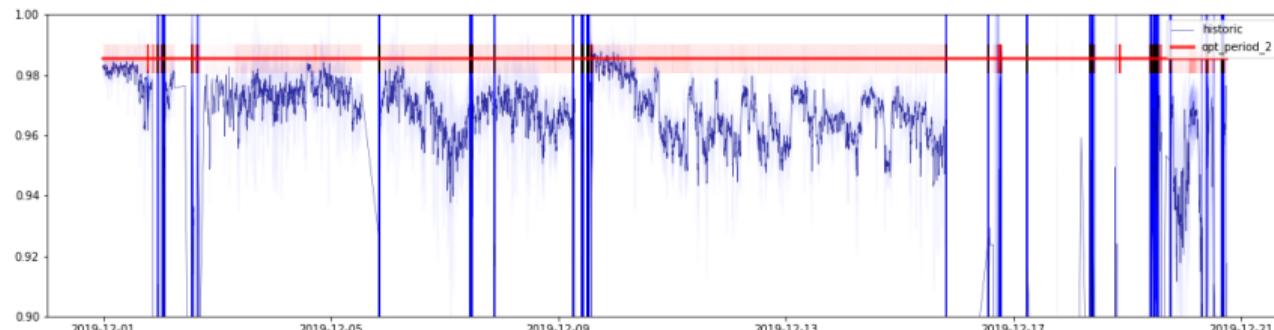

Observed states + actions + rewards:

The 2nd exploitation period (18:42 - 19:01) achieved a mean efficiency of $97.11 \pm 2.09\%$

Restricted to multibunch injections the mean efficiency was $98.56 \pm 0.46\%$

After long interruptions of the machine operation, the booster current tends to be low - as for today, **manual parameter tuning** is required.

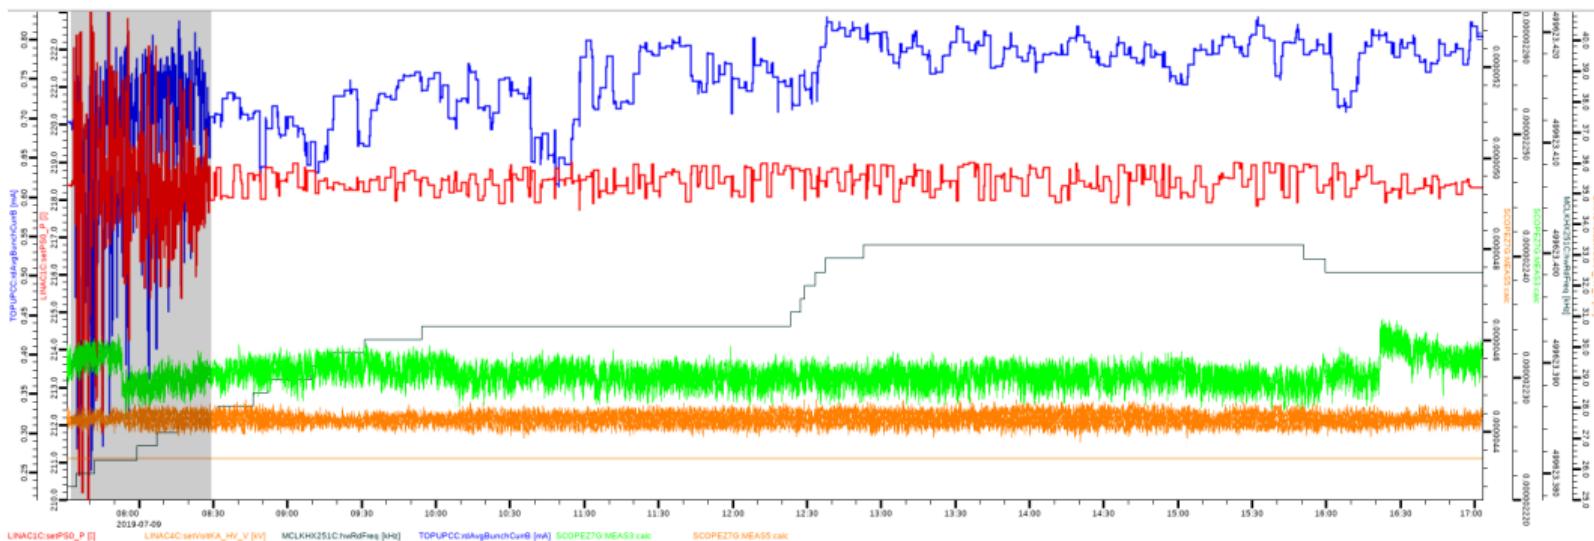

We seek an automated, RL-based solution.

- ▶ State variables:
 - ▶ High (radio) frequency - master clock.
 - ▶ Voltage in LINAC.
 - ▶ Klystron current diagnostic measurements.
- ▶ Action variable: **time phase in LINAC.**
Observations show that this parameter does not affect the injection efficiency.
- ▶ Reward: (normalized) **booster current per bunch.**

Exploration is scheduled in the meantime between injections to avoid disturbing user activity - optimization activated shortly before each injection.

- ▶ Reward in blue, action in red - remaining lines correspond to state variables.
- ▶ Pretraining with 30 days of historical data. Exploration with automatic schedule shaded - **first hour**.
- ▶ The agent optimizes (and learns) successfully during the next **8.5 hours of user operation**.

Horizontal beam motion spectrum **with fast orbit correction:**

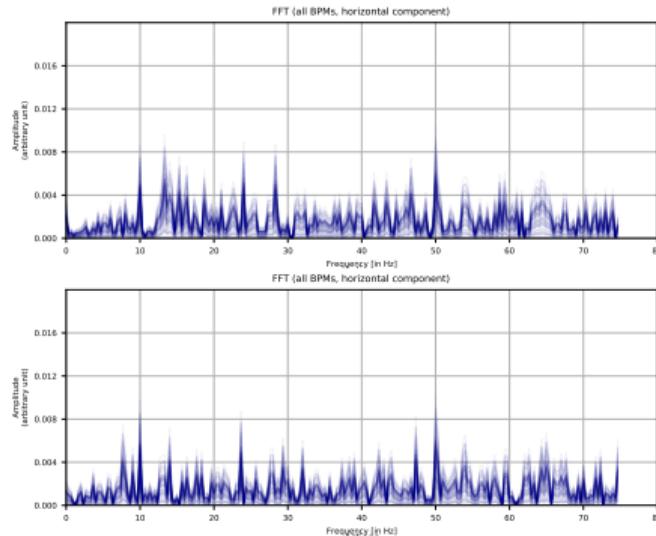

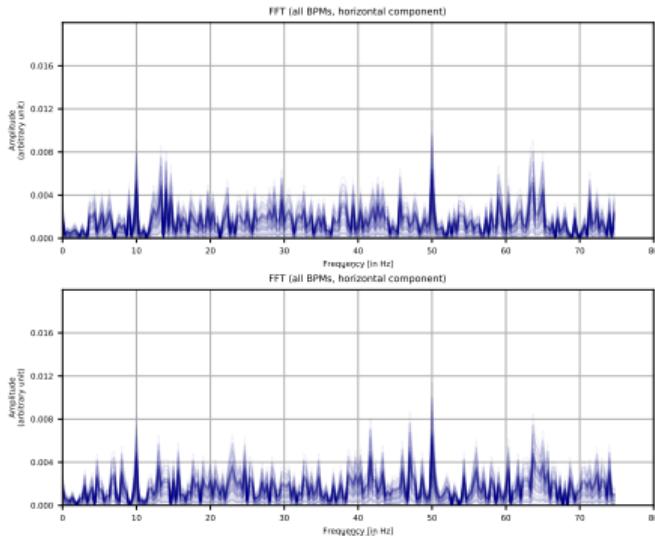

Horizontal beam motion spectrum **with fast orbit correction:**

Is it possible to mitigate the perturbations in the range 10-30Hz with a RL Agent?

Simulation of perturbed beam motion spectrum (horizontal quadrupole offset perturbed)

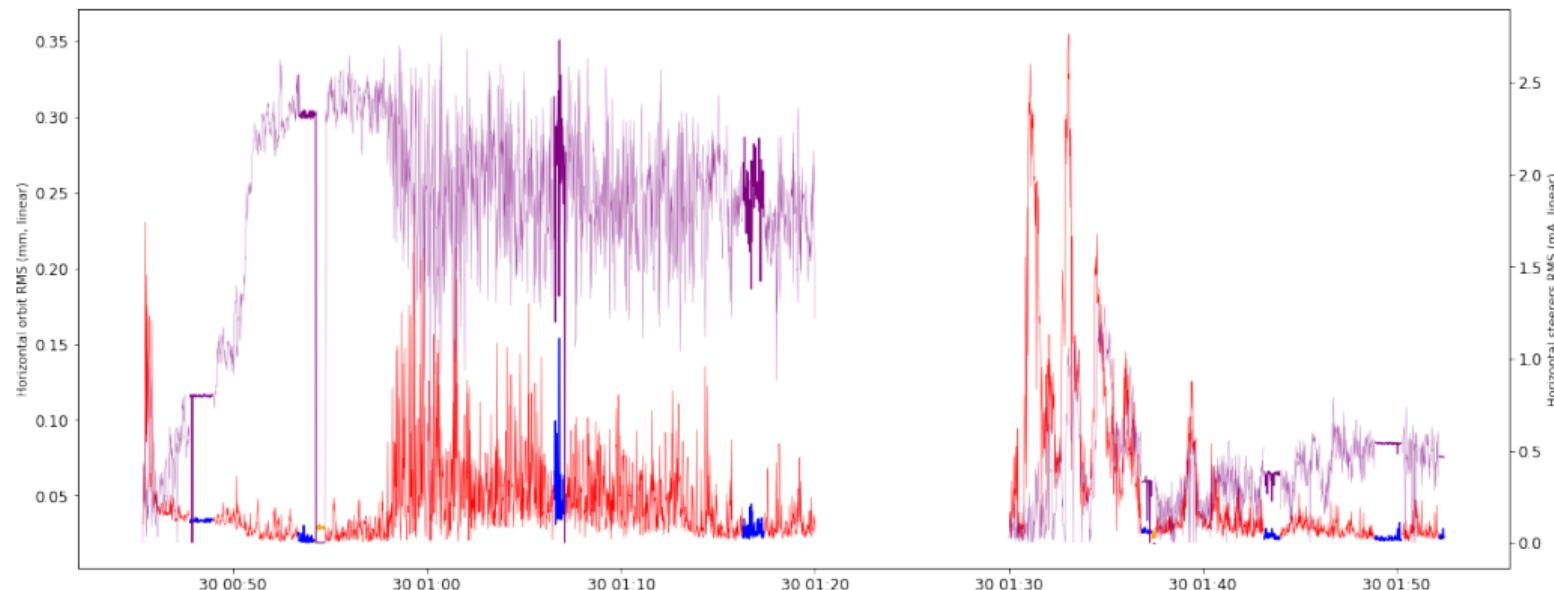

Simulation of perturbed beam motion spectrum **corrected with RL-Agent**

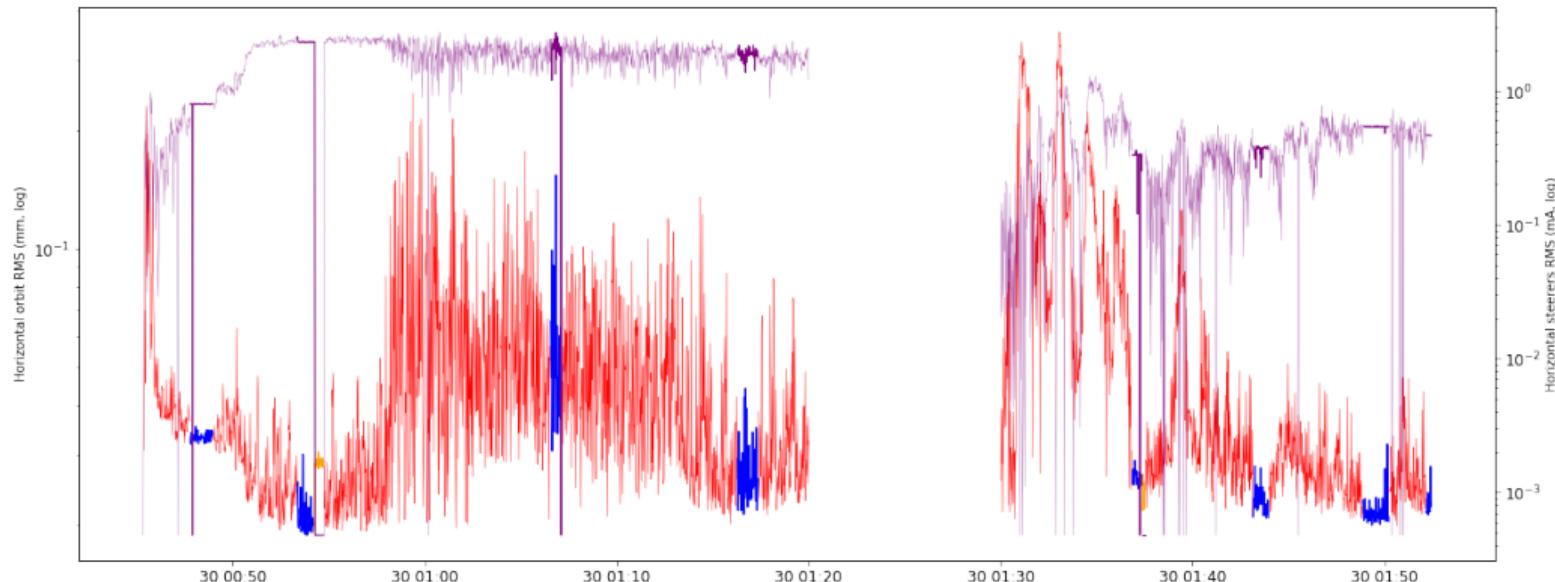

- ▶ In July 2020 we managed to set up the infrastructure for RL-based correction of harmonic perturbations during machine commissioning.
 - First *plausibility tests* of the Naus-based framework **up to 20Hz** were carried out successfully.
- ▶ In September 2020 we carried out new tests, focussing on the code performance in order to accelerate the interaction loop and so get first meaningful learning results.
 - A direct zmq-communication with the mBox (fast orbit correction infrastructure) was established, allowing an acceleration of the RL-interaction loop **up to 100Hz**.

Comparison of BPM and steerers motion (RMS, Archiver data):

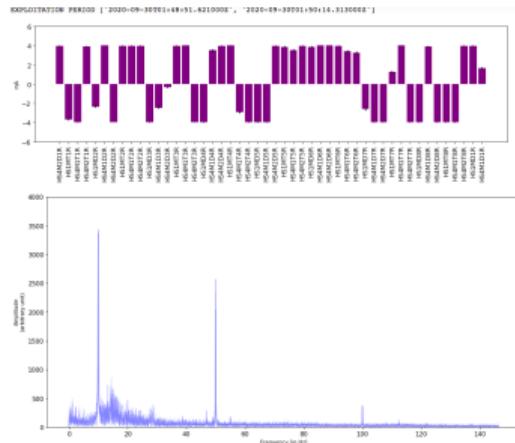

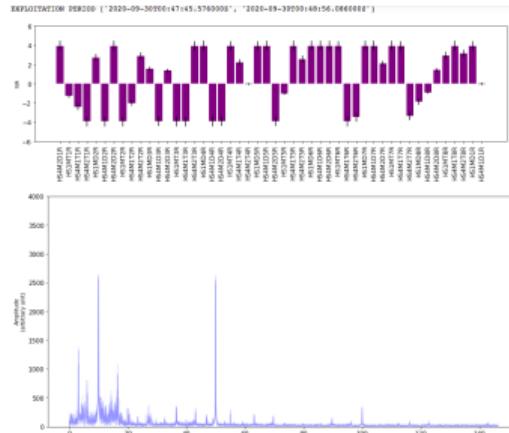

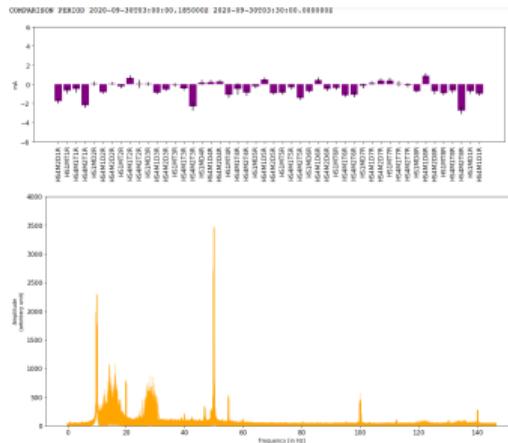

BPM RMS norm: red = exploration, blue = exploitation, orange = agent off (comparison)
Learning rate: learn at every step at ~ 26.6 Hz (left); learn after 50 steps at ~ 100 Hz (right)

- ▶ A computer model of the real machine allowing, among others:
 - ▶ simulations with actual machine setting
 - ▶ forecast of machine performance
 - ▶ linear and non-linear modelling

From the ML-perspective it will represent a major improvement → faster development since less commissioning time needed, common interfaces...

We aimed to create an interaction framework whose interfaces remained completely unchanged when training a RL-model with simulations or at the real machine. For this we used **Naus**, based on **bluesky** and **ophyd**.

- ▶ Deep Deterministic Policy Gradient
 - [LHP⁺16]: Actor-Critic Reinforcement Learning algorithm for continuous environments.
- ▶ The **Q-function** (estimation of the future reward for a given state-action pair) and the **policy** (map between states and actions) are *approximated* with Neural Networks.

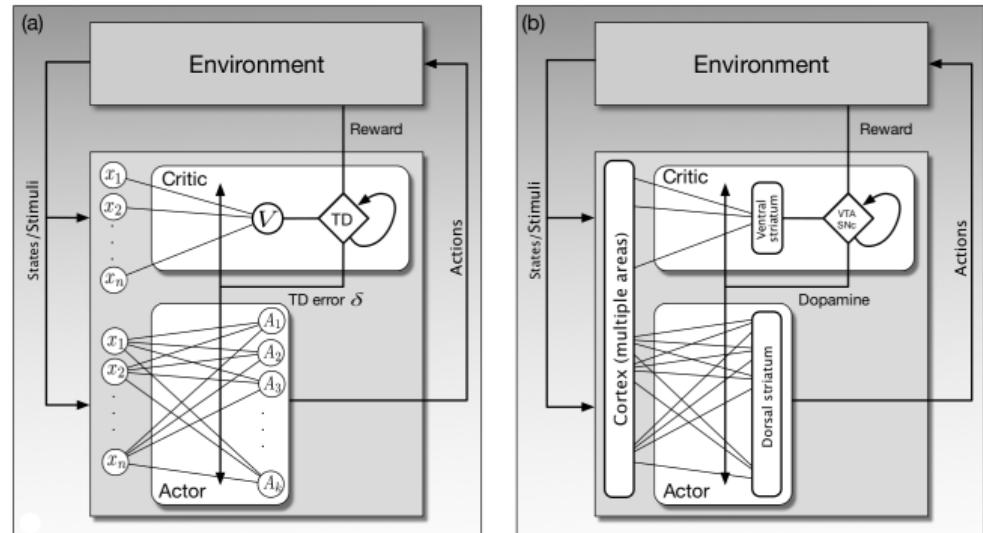

Figure: From [SB18]

- ▶ DDPG needs several implementation tricks: delayed target networks ($Q_{\tilde{\omega}}$, $\mu_{\tilde{\theta}}$), replay buffer...
- ▶ **Critic update** with stochastic behavior policy β and loss¹:

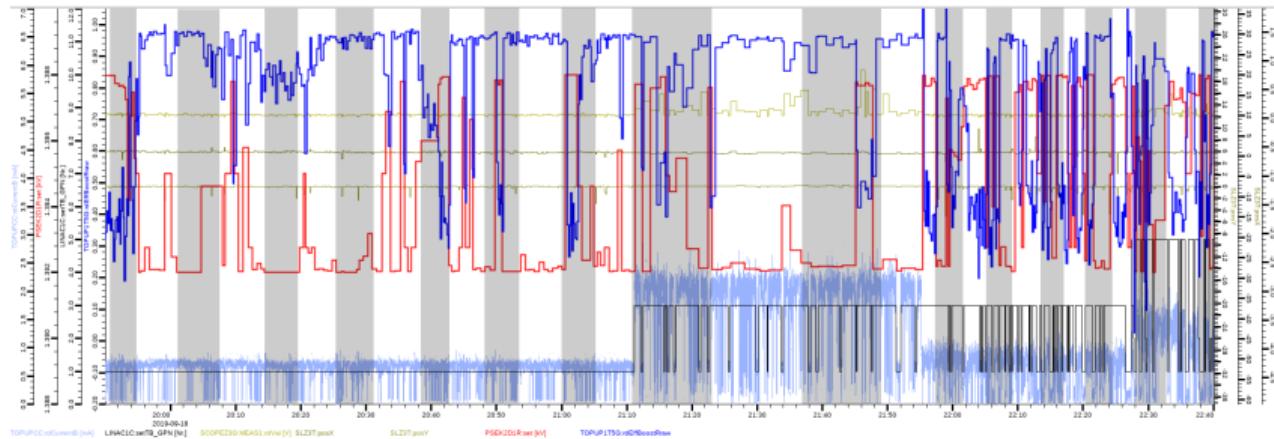

$$L(\omega) = \mathbb{E}_{s_t \sim \rho^\beta, a_t \sim \beta} \left[\left(Q_\omega(s_t, a_t) - (r(s_t, a_t) + \gamma Q_{\tilde{\omega}}(s_{t+1}, \mu_{\tilde{\theta}}(s_t))) \right)^2 \right]$$

- ▶ **Actor update** - (off-policy) Deterministic Policy Gradient Theorem ([SLH⁺14]): for the performance objective $J_\beta(\mu_\theta) = \mathbb{E}_{s \sim \rho^\beta} [Q^{\mu_\theta}(s, \mu_\theta(s))]$,

$$\nabla_\theta J_\beta(\mu_\theta) \approx \mathbb{E}_{s \sim \rho^\beta} [\nabla_\theta \mu_\theta(s) \nabla_a Q^{\mu_\theta}(s, a) \Big|_{a=\mu_\theta(s)}]$$

¹In [SLH⁺14], $\rho^\beta(s') := \int_S \sum_{t=1}^{\infty} \gamma^{t-1} p_0(s) p(s \rightarrow s' | t, \beta) ds$

- ▶ Long training time and normalization problems → improved through **demonstration with historical data** (inspired by [ZM18]).
- ▶ Slow *reaction time* to reward modifications → improved with low γ .
- ▶ Non-optimal exploration → improved with **Parameter Space Noise** ([PHD⁺17]).

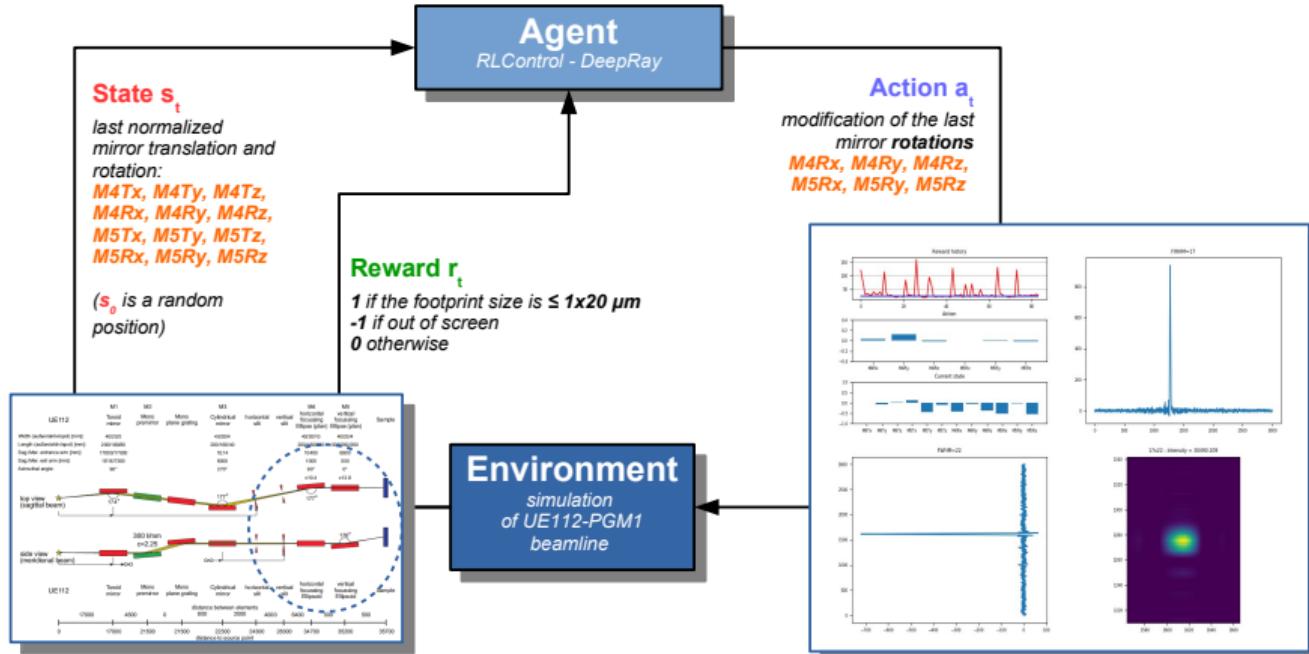

- ▶ Neural networks: `relu` used as inner activation function and `adam` as optimizer ($\text{lr} = 0.001$).
 - ▶ Critic network: five hidden layers (50+100+50+20+10 neurons) and concatenates actions at the first hidden layer. Linear activation at the output layer.
 - ▶ Actor network: three hidden layers (50+20+10 neurons). `tanh` used as activation for the output layer.
- ▶ Data preprocessing: $[-1, 1]$ linear normalization, one year historical data reduced to injections.
- ▶ Parameter Space Noise: $\delta = 0.01$.
- ▶ Training parameters: $\gamma = 0.2$, pretraining with 10000 steps (2000 before actor training), warm-up with 32 steps, target model update rate = 0.1.

- ▶ Neural networks: `relu` used as inner activation function and `adam` as optimizer ($\text{lr} = 0.001$).
 - ▶ Critic network: five hidden layers (25+50+25+10+5 neurons) and concatenates actions at the first hidden layer. Linear activation at the output layer.
 - ▶ Actor network: three hidden layers (25+10+5 neurons), all of them with layer normalization ([BKH16]). `tanh` used as activation for the output layer.
- ▶ Data preprocessing: $[-1, 1]$ linear normalization, historical data downsampled to 60 seconds.
- ▶ Parameter Space Noise: $\delta = 0.01$.
- ▶ Training parameters: $\gamma = 0.2$, pretraining with 10000 steps (2000 before actor training), warm-up with 32 steps, target model update rate = 0.1.
- ▶ *Brute-force* synchronization: update every **2 seconds** through EPICS.

- ▶ **Step**: rotation update (with fixed maximum step size) and raytracing
- ▶ **Episode**: end after a fixed number of steps or after getting reward ± 1

- ▶ Neural networks: tanh used as inner activation function and adam as optimizer ($\text{lr} = 0.001$).
 - ▶ Critic network: five hidden layers (250+500+250+100+50 neurons) and actions concatenated at the first hidden layer. Linear activation at the output layer.
 - ▶ Actor network: three hidden layers (250+100+50 neurons).
- ▶ Data preprocessing: $[-1, 1]$ linear normalization.
- ▶ Parameter Space Noise: $\delta = 0.05$.
- ▶ Training parameters: $\gamma = 0.99$, warm-up with 32 steps, target model update rate = 0.01

Environment:

- ▶ Simulated perturbation applied to **Q4M2D1R.dx** (horizontal offset of the quadrupole) with resolution = 150Hz
- ▶ x component of the BPM (beam position monitor) **BPMZ6D1R** read with **windows size = 30** (\rightarrow **state**)

→ the RL Agent *stays in the time domain!*

- ▶ Horizontal steerer **HS4M2D1R** modified (\rightarrow **action**)
- ▶ The **reward** is defined through $2e^{-c\sqrt{\frac{\sum_i x_i^2}{N}}} - 1$, where x_i denotes the horizontal component at each BPM, N is the number of BPMs and c is a normalization constant (in these simulations $c = 10000$)

DDPG agent:

- ▶ Actor network with 500-200-100 neurons, `relu` as inner activation function (output with `tanh`)
- ▶ Critic network 500-(500+action)-200-100 neurons, `relu` as inner activation function
- ▶ $\gamma = 0.9$
- ▶ Exploration with
 - ▶ Ornstein-Uhlenbeck process
 - ▶ Parameter Space Noise ([PHD⁺17])

DDPG agent:

- ▶ Actor network with 1250-500-250 neurons, `relu` as activation function (output with `tanh`)
- ▶ Critic network 1250-(1250+action)-500-250 neurons, `relu` as activation function
- ▶ $\gamma = 0.1$
- ▶ Exploration with Ornstein-Uhlenbeck process

Environment - BESSY II:

- ▶ **State:** all active BPMs (102) with window size 10.
- ▶ **Action:** all horizontal steerers (48) modified up to ± 4 mA.
- ▶ **Reward:** exponential transformation of the BPM norm: $2e^{-10\sqrt{\frac{\sum_{i=1}^{102} x_i^2}{102}}} - 1$
