

Background Studies

based on Yan's simulations at TAU

Shan Huang (shan.huang@desy.de)

17 December 2020

Yan's simulations

(03 Dec - 15 Dec)

- electron only background simulation
- 38 runs x 800 “.mac” per run
- 25k electron per “.mac”
- some failed runs (28725 successes)
- $28725 \times 25k = \underline{722M} \sim 1/2 \text{ BX}$
- *Summation over all...*

The key questions

- How many (backscattered) background particles entered ECAL and their energy deposit
- What's the background's distribution in ECAL
- What's the source's distribution?
- How does source to edeps be connected?

Tracks per file, 64k tracks totally

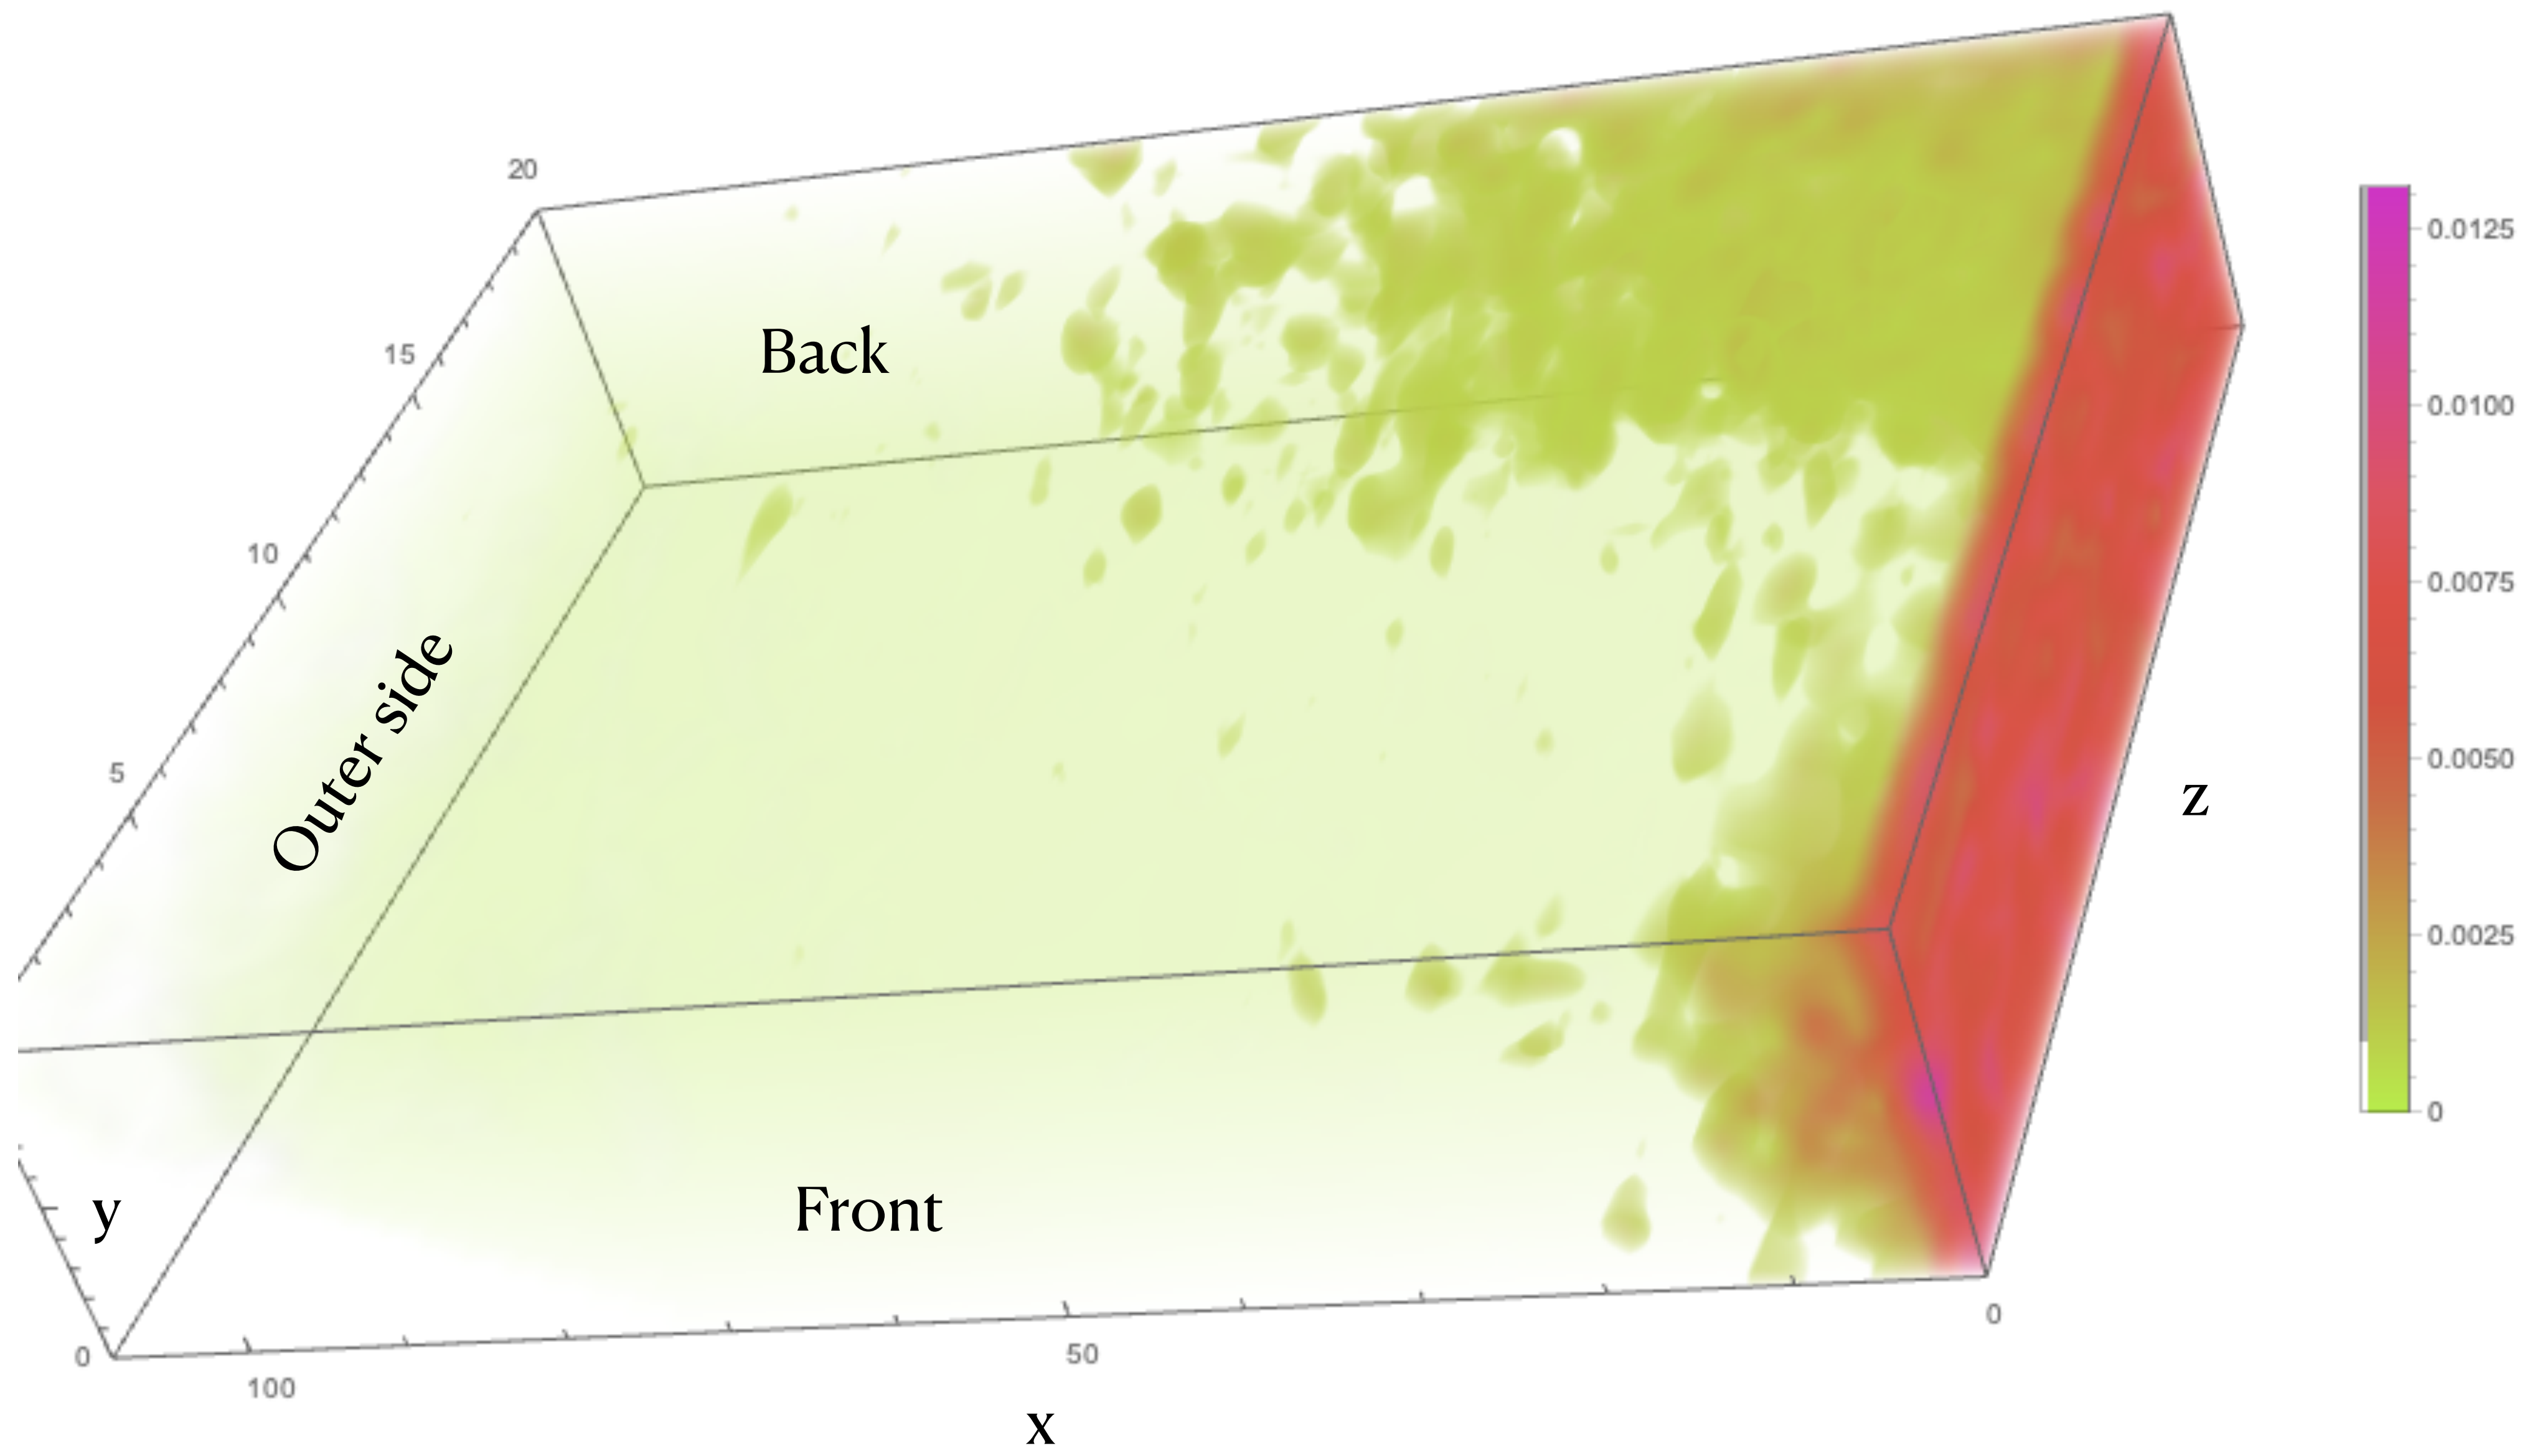

Hits per file, 47k hits totally

Deposit energy

Problem: Goes from Hits tree to Tracks tree...

Hits total: 8.3 GeV

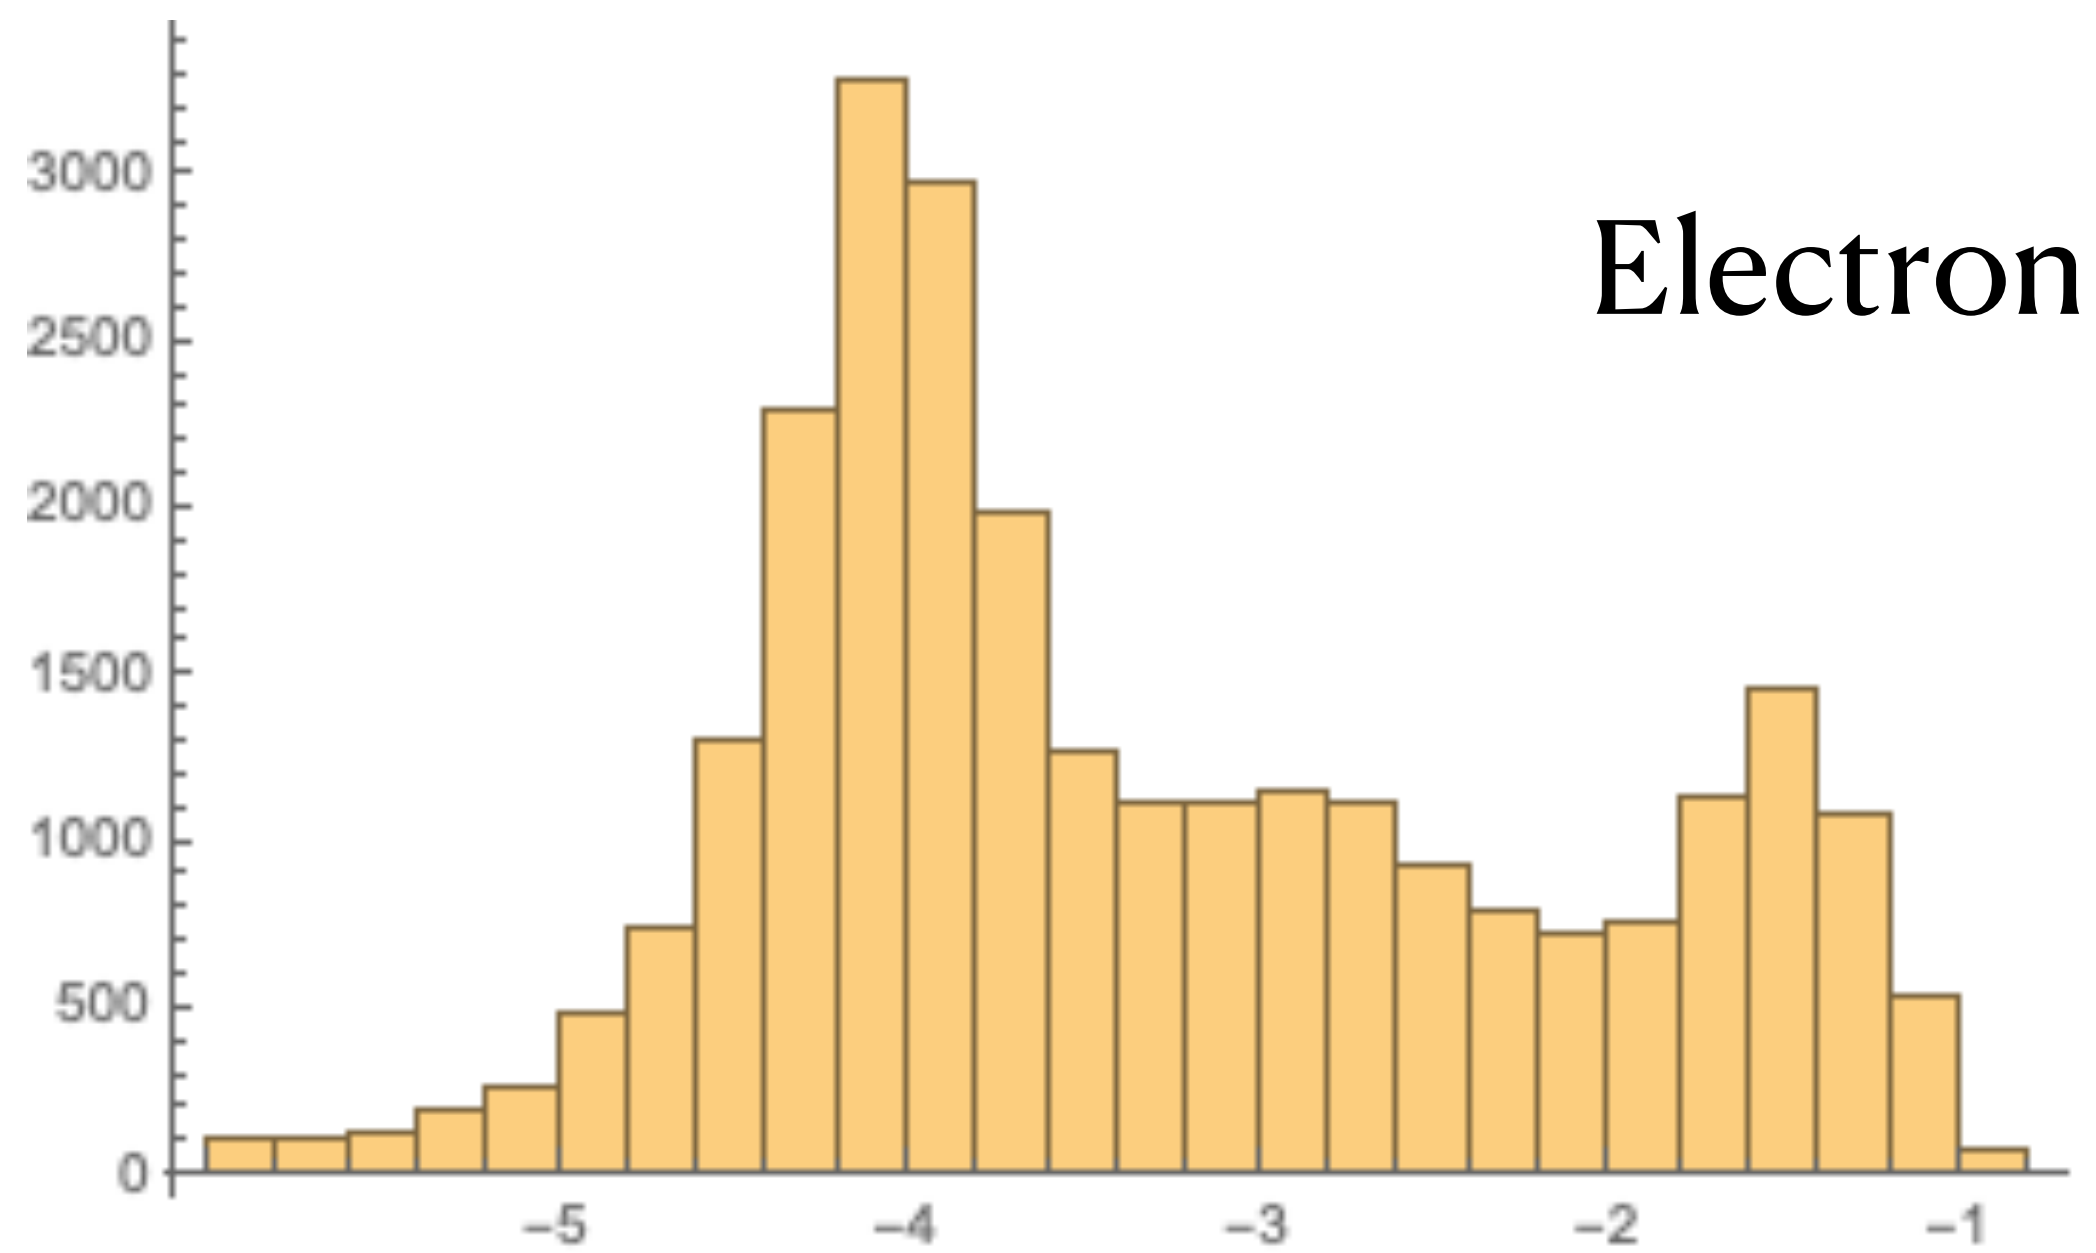

Goto Tracks tree with same
eventid and trackid and detid
Obtained 60k tracks (< 64k)

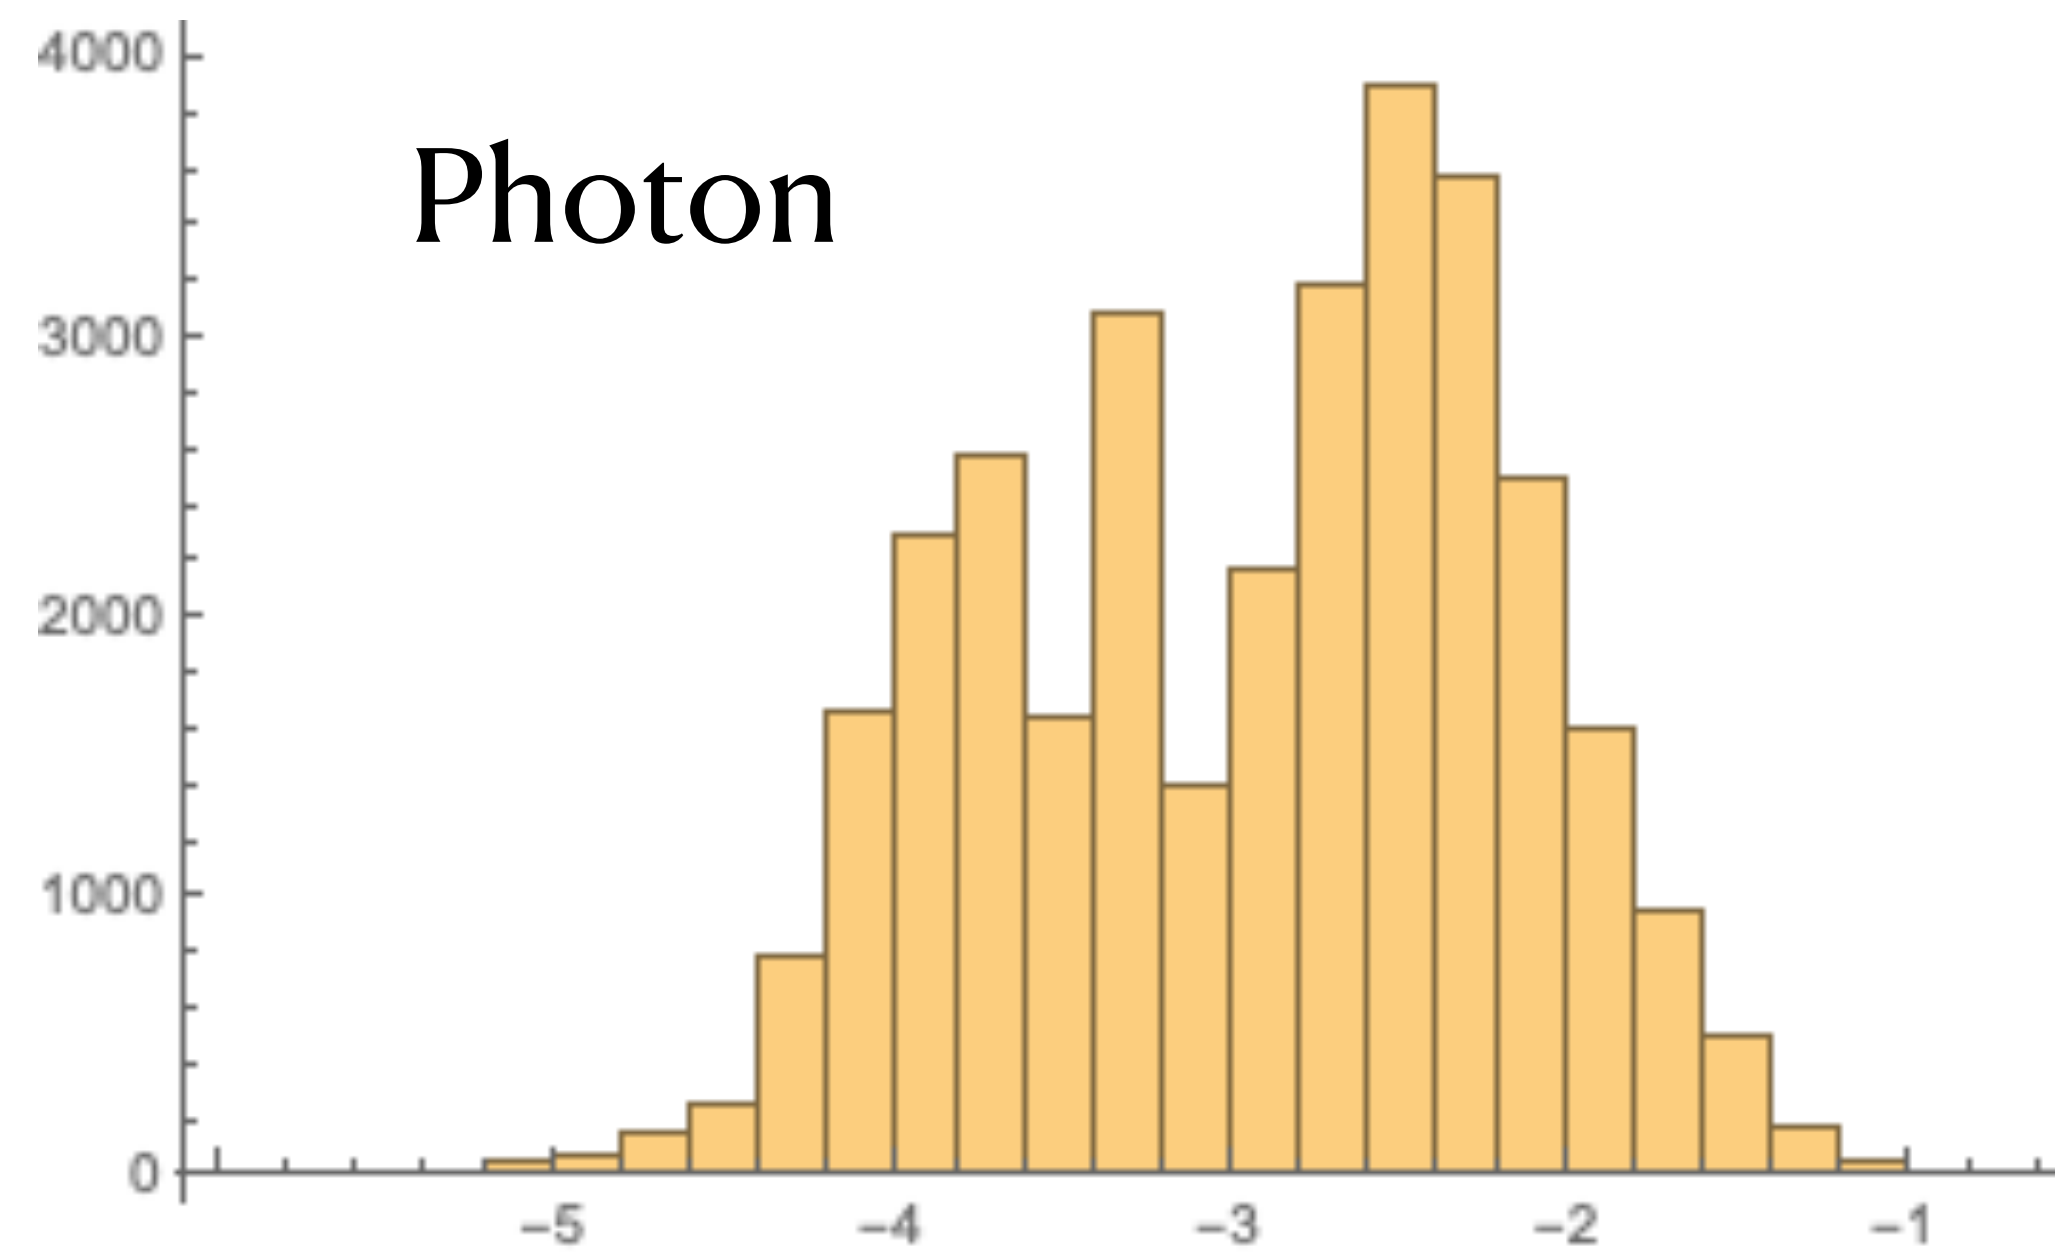

However...

- BG Photons: 132 GeV
- BG Electrons: 201 GeV
- BG Positrons: 1.4 GeV

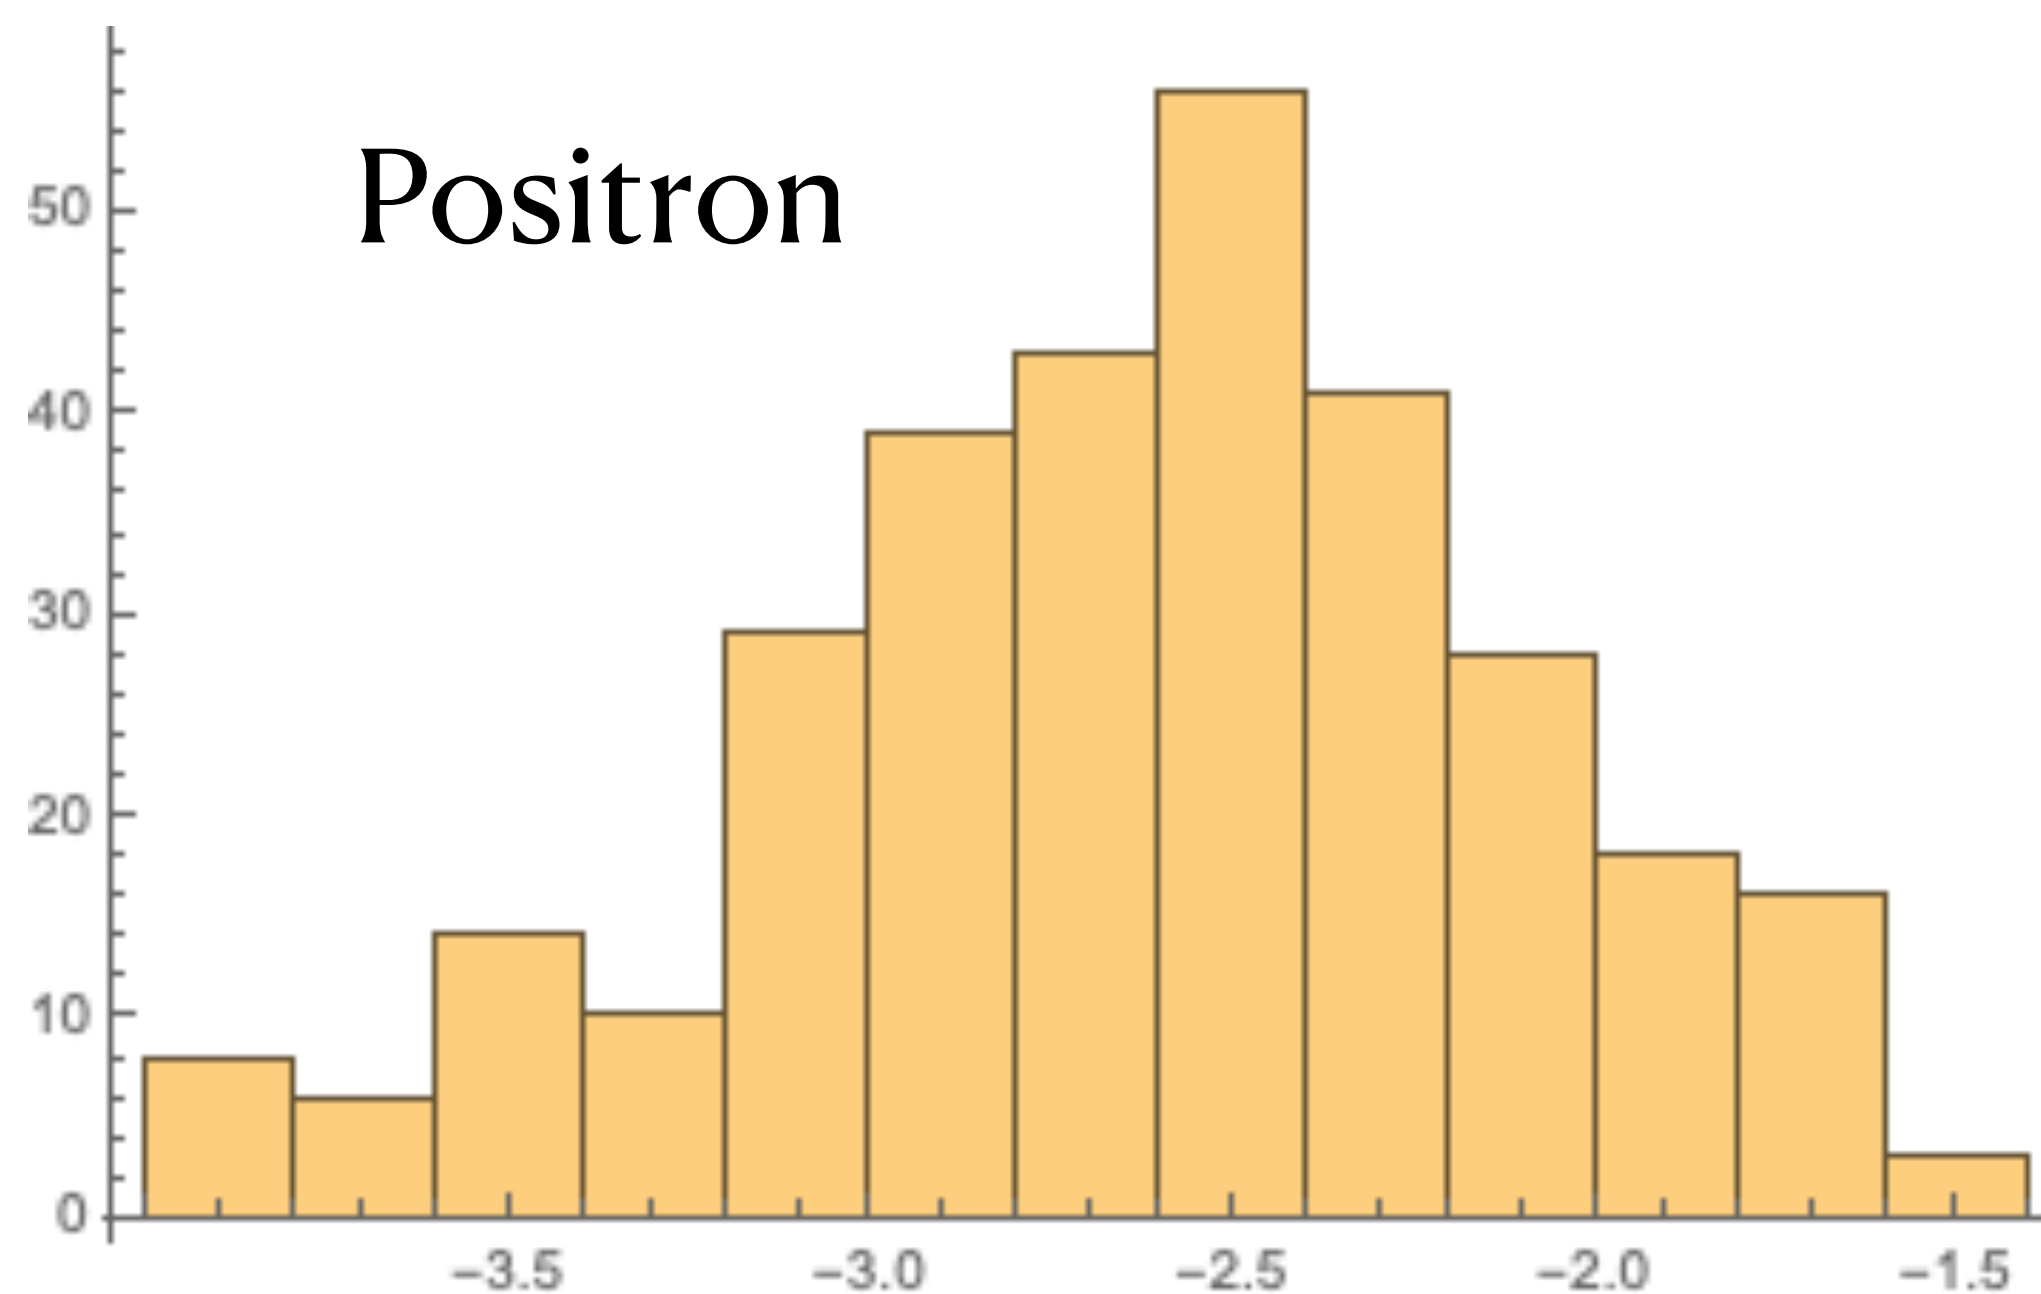

BG particles passing through?
Over-counting?

$\text{Log}(E/\text{GeV})$

$\text{Log}(E/\text{GeV})$

$\text{Log}(E/\text{GeV})$
