Automated Evaluation of the α^5 Term of Lepton g - 2: Progress Report

presented at

Loops and Legs in Quantum Field Theory 2006

Eisenach, Germany, April 23-28, 2006

Toichiro Kinoshita Laboratory of Elementary-Particle Physics Cornell University, Ithaca, New York U. S. A. 14853 in collaboration with T. Aoyama, M. Hayakawa, and M. Nio Theoretical Physics Laboratory, RIKEN Wako, Saitama, Japan 351-0198

1. Introduction

- This is a progress report of our work on the α^5 term of lepton g-2 which began more than two years ago.
- In this talk I will focus on the 10th-order diagrams that have no closed lepton loop (called *q-type*).
- These diagrams are extremely large and complicated and hardest to evaluate of all 10th-order diagrams.
- It would be practically impossible to evaluate them without highly automated algorithm.
- Initial reports on automation are given in

T. Aoyama, M. Hayakawa, T. Kinoshita and M. Nio, Nucl. Phys. B 740, 138 (2006).

- **2.** Electron g 2: Measurement.
 - In 1987 the value of electron g-2 was improved over previous best value by three orders of magnitude in a Penning trap experiment by Dehmelt et al. at U. of Washington.

Van Dyck et al., PRL 59, 26 (1987)

• Their final results were:

 $\mathbf{a_{e^-}} = 1\ 159\ 652\ 188.4\ (4.3) imes\ 10^{-12}$

 ${f a_{e^+}}=1\;159\;652\;187.9\;(4.3) imes\;10^{-12}$

• Reanalysis of these data and their combination assuming CPT invariance leads to

 ${f a_e}[{f UW87}] = 1\;159\;652\;188.3\;(4.2) imes\;10^{-12}$

Mohr and Taylor, RMP 77, 1 (2005)

- Measurement uncertainty was dominated by cavity shift due to interaction of electron with hyperboloid cavity which has complicated resonance structure.
- Several ways to reduce this error examined: (a) Use cavity with smaller Q.

van Dyck, et al., 1991, unpublished.

(b) Study cavity shift of many (~ 1000)-electron cluster.

Mittleman, et al., PRL 75, 2839 (1995)

(c) Use cylindrical cavity, whose property is known analytically.

Brown, Gabrielse, RMP 58, 233 (1986)

- Gabrielse's new measurement of a_e is based on (c).
 - A preliminary result was reported:

 $a_{e^{-}}[HV05] = 1\ 159\ 652\ 180.86\ (0.57) \times\ 10^{-12}$ (0.49 ppb)

B. Odom, PhD thesis, Harvard University, 2005

- 7.5 times more precise than the Seattle result.
- Another set of measurements has just been finished.
- The new result ?

3. Theory of Electron g - 2 up to Order α^4

$$\begin{split} \mathbf{a}_{e}(\mathbf{QED}) &= \mathbf{A}_{1} + \mathbf{A}_{2}(\mathbf{m}_{e}/\mathbf{m}_{\mu}) + \mathbf{A}_{2}(\mathbf{m}_{e}/\mathbf{m}_{\tau}) + \mathbf{A}_{3}(\mathbf{m}_{e}/\mathbf{m}_{\mu},\mathbf{m}_{e}/\mathbf{m}_{\tau}) \\ \mathbf{A}_{i} &= \mathbf{A}_{i}^{(2)}\left(\frac{\alpha}{\pi}\right) + \mathbf{A}_{i}^{(4)}\left(\frac{\alpha}{\pi}\right)^{2} + \mathbf{A}_{i}^{(6)}\left(\frac{\alpha}{\pi}\right)^{3} + \dots, \ \mathbf{i} = \mathbf{1},\mathbf{2},\mathbf{3} \\ \mathbf{A}_{1}^{(2)} &= \mathbf{0}.\mathbf{5} & \mathbf{1} \ \mathbf{diagram} \ (\mathbf{analytic}) \\ \mathbf{A}_{1}^{(4)} &= -\mathbf{0}.328 \ \mathbf{478} \ \mathbf{965} \ \dots & \mathbf{7} \ \mathbf{diagrams} \ (\mathbf{analytic}) \\ \mathbf{A}_{1}^{(6)} &= \mathbf{1}.181 \ \mathbf{241} \ \mathbf{456} \ \dots & \mathbf{72} \ \mathbf{diagrams} \ (\mathbf{numerical}, \mathbf{analytic}) \\ &\qquad \mathbf{Kinoshita}, \ \mathbf{PRL} \ \mathbf{75}, \ \mathbf{4728} \ (\mathbf{1995}) \\ \mathbf{Laporta}, \ \mathbf{Remiddi}, \ \mathbf{PLB} \ \mathbf{379}, \ \mathbf{283} \ (\mathbf{1996}) \\ \mathbf{A}_{1}^{(8)} &= -\mathbf{1}.\mathbf{728} \ \mathbf{3} \ (\mathbf{35}) & \mathbf{891} \ \mathbf{diagrams} \ (\mathbf{numerical}) \\ &\qquad \mathbf{Kinoshita}, \ \mathbf{Nio}, \ \mathbf{Phys}. \ \mathbf{Rev.} \ \mathbf{D} \ \mathbf{73}, \ \mathbf{0}\mathbf{13003} \ (\mathbf{2006}) \end{split}$$

- Error of $A_1^{(8)}$ reduced to one-tenth of old one.
- $ullet \mathbf{A}_2 \ ext{term is small} :\sim 2.72 imes 10^{-12}.$
- •A $_3$ term is even smaller :~ 2.4×10^{-21} .
- $\bullet Non-QED \ term \ (Standard \ Model) \ is \ small, \ too: 1.70(2)\times 10^{-12}.$
- This is why a_e provides a very good test of QED.

- To compare theory with measurement we need α .
- At present best α available are

$$lpha^{-1}(\mathbf{h}/M_{Rb}) = \mathbf{137.035} \ \mathbf{998} \ \mathbf{78} \ (\mathbf{91}) \qquad [\mathbf{6.7 \ ppb}]$$

P. Cladé et al., PRL 96, 033001 (2006)

$$\begin{split} &\alpha^{-1}(\mathbf{h}/M_{Cs}) = 137.036\ 000\ 1\ (11) & [7.7\ \mathrm{ppb}] \\ & \text{Wicht, Hensley, Sarajlic, Chu, Physica Scripta T102, 82-88 (2002)} \\ \bullet \ \mathrm{Assuming}\ \mathbf{A}_1^{(10)} = 0.0(3.8)\ (\text{pure guess by Mohr-Taylor})\ \text{we obtain} \\ & \mathbf{a}_{\mathrm{e}}(\mathbf{h}/\mathbf{M}_{\mathrm{Rb}}) = 1\ 159\ 652\ 188.70\ (0.10)(0.26)(7.71)\times\ 10^{-12} \\ & \mathbf{a}_{\mathrm{e}}(\mathbf{h}/\mathbf{M}_{\mathrm{Cs}}) = 1\ 159\ 652\ 177.55\ (0.10)(0.26)(9.32)\times\ 10^{-12} \\ & (8\mathrm{th})(10\mathrm{th})(\alpha(h/M)) \end{split}$$

and

$$egin{aligned} \mathbf{a_e}[\mathbf{HV05}] - \mathbf{a_e}(\mathbf{h}/\mathbf{M_{Rb}}) &= -7.8~(7.8) imes~10^{-12} \ \mathbf{a_e}[\mathbf{HV05}] - \mathbf{a_e}(\mathbf{h}/\mathbf{M_{Cs}}) &= -3.3~(9.4) imes~10^{-12} \end{aligned}$$

- Striking feature of $a_e(h/M_{Rb})$ and $a_e(h/M_{Cs})$ is that their errors come predominantly from measurements of α .
- This means that non-QED α , even the best ones, is too crude to test QED to the extent made possible by the progress of theory and measurement of a_e .
- Instead we can turn the argument around and calculate α assuming that QED is still valid.
- This yields very precise values:

 $\alpha^{-1}(a_e[UW87]) = 137.035\ 998\ 834\ (12)(31)(502)\ [3.7\ ppb]$

 $\alpha^{-1}(a_e[HV05]) = 137.035\ 999\ 708\ (12)(31)(68)\ [0.55\ ppb]$

- Fig. 1 gives graphic comparison of some α 's.
- To show finer details of lower half the horizontal scale is enlarged by 10 in Fig. 2.

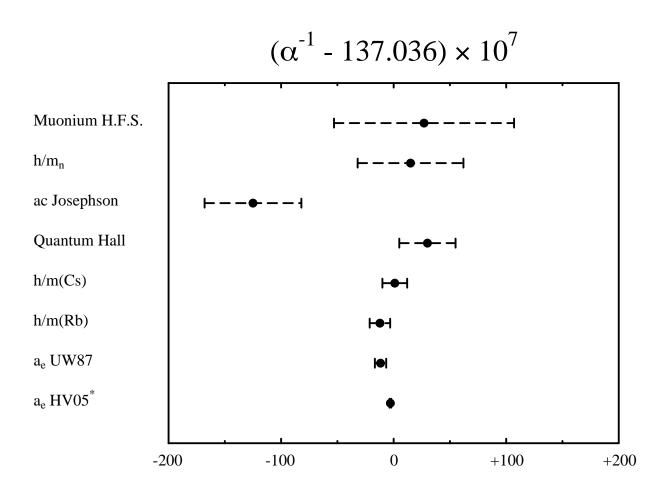

Figure 1: Comparison of various α^{-1} . $\alpha(h/m_{Cs})$ may be improved by factor 2. The superscript * on a_e HV05* means that the corresponding α is still tentative.

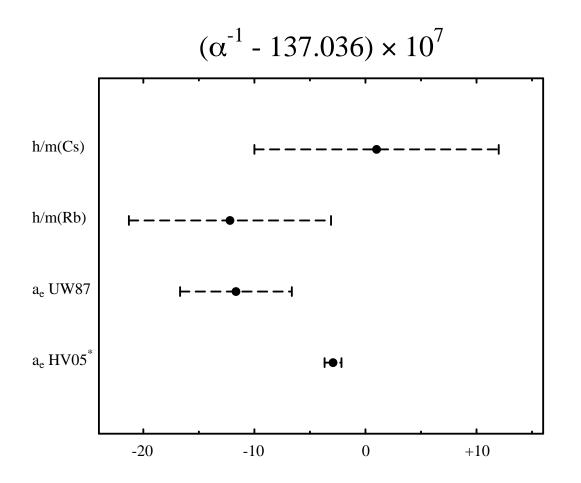

Figure 2: Magnification of the lower half of Fig. 4 by factor 10.

- 4. Tenth-order term: Why needed ?
 - Uncertainty in $\alpha(a_e[HV05])$ is only factor 2 larger than that of theory, which is mostly from the α^5 term.
 - Thus, when measurement improves by just factor 2, an actual value of α^5 term becomes necessary to improve $\alpha(a_e)$ further.
 - This is why the α^5 term deserves serious investigation.
 - 12672 Feynman diagrams contribute to the α^5 term.
 - Real challenge to tackle such a gigantic problem.
 - First step: Classify all diagrams into gauge-invariant sets.
 - There are 32 g-i sets within 6 supersets as shown next.

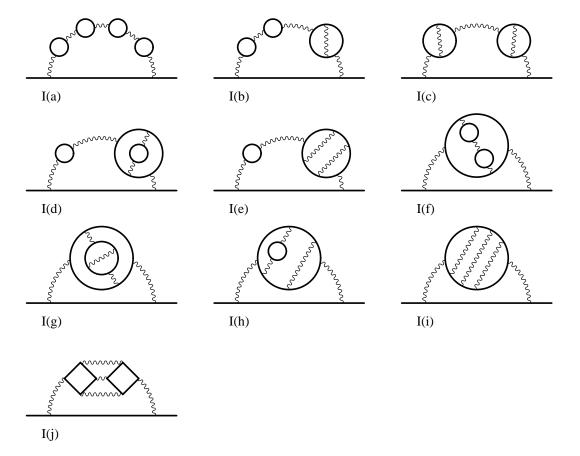

Figure 3: Self-energy-like diagrams representing 208 vertex dgrms of set I.

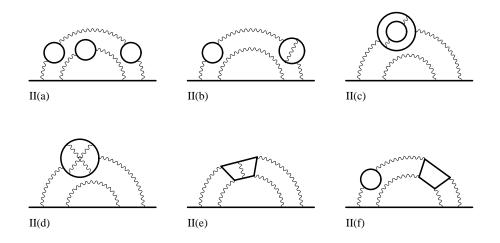

Figure 4: Diagrams of Set II which consists of 600 vertex diagrams.

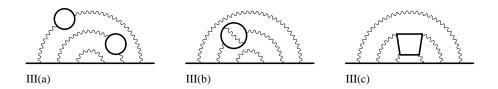

Figure 5: Diagrams of Set III which consists of 1140 vertex diagrams.

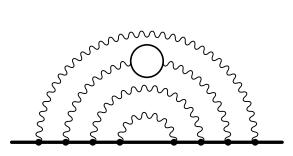

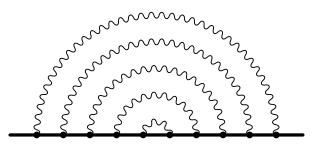

Figure 6: Diagrams of Set IV which consists of 2072 vertex diagrams.

 $_{\rm Figure 7:}$ Diagrams of Set V which consists of 6354 vertex diagrams.

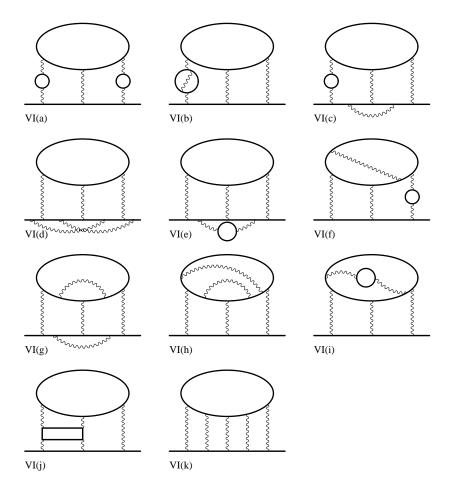

Figure 8: Diagrams of Set VI which consists of 2298 vertex diagrams.

- Largest and most difficult is the Set V, which consists of 6354 Feynman diagrams of "q-type".
- We are thus focused on Set V since others, being less complicated, are easier to handle.
- Set V has a simplifying feature that sum of nine vertex diagrams can be related to one self-energy diagram by

$$\Lambda^{
u}(\mathbf{p},\mathbf{q})\simeq -\mathbf{q}_{\mu}[rac{\partial\Lambda_{\mu}(\mathbf{p},\mathbf{q})}{\partial\mathbf{q}_{
u}}]_{\mathbf{q}=\mathbf{0}}-rac{\partial\Sigma(\mathbf{p})}{\partial\mathbf{p}_{
u}}$$

derived from the Ward-Takahashi identity.

- This enables us to reduce number of diagrams to 706.
- Time-reversal invariance reduces it further to 389 shown in the next page.

Figure 9: Overview of all diagrams contributing to Set V.

- Analytic integration is likely to be far in the future.
- Numerical integration is the only viable option at present.
- Fortunately, algebraic part of manipulation developed for α^3 case and extended for α^4 applies to α^5 , too.
- For α^5 , however, every step must be fully automated.
- Also, master code is needed to run all steps automatically.
- Let us now sketch these steps.

- Step I: Diagram generation
 - Each (q-type) diagram is expressed by a single-line code which specifies pattern of pairing of vertices by photon propagators.
 - Algorith implemented by C++.
 - Diagrams are named X001,..., X389 and stored as plaintext file.
 - This file enables us to identify all UV divergent subdiagrams according to certain algorithm.
 - Implemented by both Perl and C++.
 - Step I is crucial for automatic control of all subsequent steps.
 - It was not needed in α^3 and α^4 cases which were simple enough to go without it.

- Step II: Construct unrenormalized integrand
 - Translate one-line rep. of diagram into integrand.
 - Carry out momentum integration analytically and express result as integral over Feynman parameters z_1, z_2, \dots, z_N , and "symbols" B_{ij}, A_i, U, V :

$$/(dz)_G J_G,$$

where

$$(dz)_G \equiv \prod_{i=1}^N dz_i \delta(1 - \sum_{i=1}^N z_i), \qquad J_G = \frac{F_0(B_{ij}, A_i)}{U^2 V^{n-1}} + \frac{F_1(B_{ij}, A_i)}{U^3 V^{n-2}} + \cdots.$$

- Previously J_G was obtained by FORM using home-made integration table written in FORM.
- Now automation of Step II proceeds as follows:
 Diagram info. → input for FORM, obtained by Perl
 → analytic integration using integration table in FORM.

- Step III: Construct building blocks
 - Get $B_{ij}, C_{i,j}, A_i, U, V$ as homog. polynomials of z_1, z_2, \ldots, z_N .
 - * U, B_{ij} are related to loop momenta, and determined by the topology of diagram.
 - $\star A_i$ are related to flow of external momenta, and satisfy Kirchhoff"s laws for "currents".
 - Easy to obtain B_{ij} , U, etc. by hand in 6th- and 8th-orders. Much harder in 10th-order.
 - We now calculate them automatically:

input info. $\rightarrow B_{ij}, C_{i,j}, U, \dots$ by MAPLE and FORM.

- They are also derived in C++.
- V has form common to all diagrams:

$$V = \sum_{i}^{electrons} z_i(1 - A_i) + \sum_{i}^{photons} z_i\lambda^2,$$

where electron mass is put to one and λ is infrared cutoff.

- Step IV: Construct UV subtraction terms
 - Most difficult part is renormalization.
 - Textbook renormalization is not suitable for putting on computer and known only to lowest order anyway.
 - We start from subtractive regularization.
 - Subtraction integrand is derived from original integrand by applying K-operation, defined for each divergent subdiagram based on simple power-counting rule.
 - Properties of *K*-operation:
 - \star Subtraction of UV divergence is pointwise.
 - \star It is built so that it factorize analytically into product of lower-order quantities, an important feature for cross-checking with other diagrams.
 - * It contains only UV-divergent part of renormalization constant. Thus additional (finite) renormalization is required.

• This subtraction scheme applied to all subdiagram divergences regularizes the original integral, yielding

$$\Delta M_G = M_G - \sum_{f \in \mathcal{F}} X_f$$
$$= \int (dz)_G [J_G - \sum_{f \in \mathcal{F}} K_f J_G]$$

where \mathcal{F} is the set of Zimmermann's forest f of divergent subdiagrams.

- IR-divergence can be handled similarly by IR power-counting rule.
- These procedures had been developed for α^3 and α^4 cases by partly-automatic means using FORM.
- Now they are fully automated:

input info. \rightarrow subtraction terms in FORTRAN

implemented by Perl with help by MAPLE and FORM.

- Step V: Residual renormalization
 - Output of Steps I IV are UV- (and IR-) finite integral.
 - However, it is not standard renormalized amplitude (although it is on-shell).
 - Finite residual renormalization must be carried out to get observable g-2.
 - Residual renormalization was easy for α^3 case and still manageable by hand for α^4 .
 - For α^5 , however, number of UV subtraction terms (each being integral of up to 8th-order) is 13150 so that summing up residual renormalization terms becomes a huge operation.
 - Number of IR subtraction terms is large, too.
 - Thus Step V must be fully automated, achieved by Perl, MAPLE, and FORM.

- Controling whole steps:
 - Each step of code generation is achieved by individual Perl program helped by MAPLE and FORM.
 - Flow of entire process governed by shell script.
 - It takes the name of diagrams (X001,...,X389) as input and performs following operations:
 - (a) Find the input information from data file prepared in Step I.
 - (b) Construct components of integration code in FORTRAN.
 - (c) Gather all FORTRAN codes in the end.
 - Step V can be attached at the end of Step IV to make the entire process automatic.
 - But we are treating Step V separately for the moment.

- Thus far we completed Steps I, II, III, IV for 135 diagrams which have only UV-divergent vertex subdiagrams.
- For 254 diagrams containing self-energy subdiagrams Steps I III have been completed.
- But Step IV requires more work because these diagrams have also logarithmic IR divergence and, in some cases, linear IR-divergence.
- Linear IR divergence is caused by our approach which splits selfmass counterterm into UV-div. and UV-finite parts and subtracts UV-divergent part only:

$$\cdots \frac{1}{\not p - m} \left((\delta m - \delta m^{UV}) + B(\not p - m) \right) \frac{1}{\not p - m} \cdots$$

- In second order case we have $\delta m \delta m^{UV} = 0$.
- However, $\delta m \delta m^{UV} \neq 0$ in other cases, which causes an extra pole in the IR limit.
- While waiting for full automation code, we decided to deal with IR problem temporarily by giving a finite cutoff to photon mass.
- To obtain better result for numerical integration it is important to subtract linear IR pole explicitly.
- At present this is done by hand, but is being automated.
- Once linear divergence is removed, logarithmic divergence can be handled easily by photon mass cutoff.

• As warm-up, we have tested this approach for sixth-order and eighth-order cases.

• α^3 case:

 q-type only
 Photon cutoff $\lambda^2 = 10^{-6}$ Exact treatment

 0.8941 (272)
 0.904979...

* All diagrams generated in 39 seconds on DEC α . * 10⁷ sampling points 50 iterations took 25 - 45 min on DEC α .

- Effect of cutoff seems to be within errorbars.
- Good agreement shows that our automating algorithm is bug-free and gives good approximate answer.

• α^4 case:

q-type onlycutoff
$$\lambda^2 = 10^{-4}$$
numerical with $\lambda = 0$ -2.1005 (1216)-1.9931 (35)

- \star All 47 diagrams generated in 1240 seconds on DEC $\alpha.$
- * 10^7 sampling points 50 iterations using 64 CPU took 8 min to 100 min.
- \star Final results required up to 150 iterations.
- Good agreement provides the confirmation of previous eighth-order code.
- This is the first independent check of the eighth-order code.

- Current status of numerical integration:
 - Crude evaluation by VEGAS of all 389 integrals has been carried out.
- Table 1 lists all diagrams with only vertex renormalization terms. Photon mass is set equal to 0.
- Tables 2 and 3 list diagrams with at least one self-energy renormalization terms, evaluated with photon mass set equal to $10^{-2}m_e$.

Table 1: 135 diagrams which have at the vertex corrections only. Phton mass is set to be zero.

- Statistics of running α^5 code:
 - \star 10 20 minutes for generation of a FORTRAN code for each diagram on DEC $\alpha.$
 - \star Typical integral consists of 90,000 lines of FORTRAN code occupying more than 6 Megabytes.
 - * 10^6 sampling points × 20 iterations takes 5 7 hours on 32 CPU PC cluster.
 - Step V for residual renormalization is being carried out.
 - We will soon have a crude value of Set V.

5. Remaining task

- Next on schedule is treatment of IR divergence by IR div. subtraction method, which enables us to put $\lambda = 0$.
- The method developed for Set V enables us to evaluate Set III(a), Set III(b), and Set IV very quickly.
- Sets I(a, b, c, d, e, f), II(a, b, f), VI(a, b, c, e, f, i, j, k) had been evaluated previously.

T. Kinoshita and M. Nio, Phys. Rev. D 73, 053007 (2006)

- Remaining sets I(g, h, i, j), II(c, d, e), III(c), and VI(d, g, h) do not seem to present particular complication except possibly for I(i), I(j), II(e).
- We will have a complete α^5 term within few years.
