6th October 2022

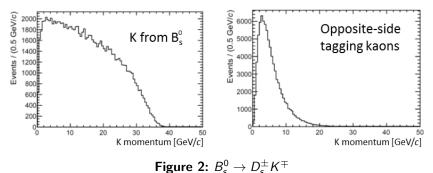

Introduction RICH detectors

- Excellent hadron PID is crucial in flavour physics
 - Resolve combinatorics and separate decay modes
- RICH detectors are very powerful for particle ID at high momentum
- At LHCb, π -K separation is excellent up to 100 GeV
- A 4π collider RICH layout was previously used at DELPHI and SLD
 Challenging because of the space required

Motivation for RICH at FCC-ee

- \bullet FCC-ee will collect 5 \times 10^{12} Z boson decays in 4 years
 - Allows for a world-leading flavour physics programme
 - Combined with excellent PID capabilities, FCC-ee will reach an unprecedented precision
- Good PID performance is also required for Higgs, WW and tt̄ physics
 In particular, kaon ID is crucial for H → ss̄

B physics requires pion-kaon separation from low momentum up to 40 GeV

Motivation for RICH at FCC-ee

- FCC-ee will collect $5 \times 10^{12} \ Z$ boson decays in 4 years
 - Allows for a world-leading flavour physics programme
 - Combined with excellent PID capabilities, FCC-ee will reach an unprecedented precision
- Good PID performance is also required for Higgs, WW and $t\bar{t}$ physics
 - In particular, kaon ID is crucial for $H
 ightarrow s ar{s}$

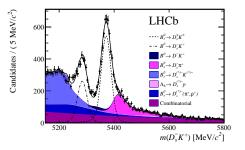

Figure 3: $B_s^0 \rightarrow D_s^{\pm} K^{\mp}$ The $B_s^0 \rightarrow D_s^{\pm} \pi^{\mp}$ background would be 10 times larger without PID capabilities!

Array of RICH Cells

- Array of RICH Cells (ARC): A novel RICH detector concept
 - First presented by R. Forty at FCC week 2021
 - Compact, low-mass solution for particle ID for FCC-ee
 - Concept inspired by the compound eyes of an insect
- Adapted to fit into the CLD experiment concept, taking 10% from the tracker volume
 - Radial depth of 20 cm, radius of 2.1 m and a length of 4.4 m
 - Aim to keep material budget below $0.1X_0$
- Aerogel and gas radiators with a spherical mirror
 - · Aerogel also acts as thermal insulation between gas and detector

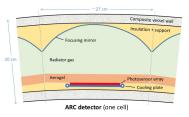

Figure 4: ARC has a cellular structure, similar to an insect's compound eyes

Original pressurised ARC

- Original idea was for a vessel with pressurised gas
 - Higher photon yield in smaller radial space
- However, a non-pressurised gas was found to have better performance, and also simplify the vessel design

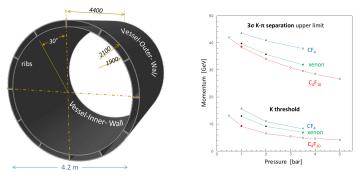

Figure 5: Layout of original carbon fiber vessel (left) and the performance at different pressures (right)

Array of RICH Cells

- Cell layout has evolved to profit from a simplified unpressurised vessel
- All cells are the same size, organised on a hexagonal grid
 - Barrel (endcap) has 945 (384) cells in total, where 18 (21) are unique
 - Hexagonal shape avoids the corners, where performance is worse

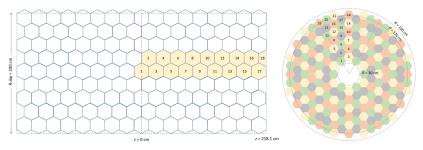

Figure 6: Barrel (left) and endcap (right) cells

ARC radiators

- *C*₄*F*₁₀:
 - Baseline assumption, well known from LHCb RICH1
 - $n = 1.0014 \implies \theta_c = 53 \text{ mrad}$, suitable for high momentum particles
 - C_4F_{10} is a greenhouse gas, substitution with pressurised Ar/Xe possible
- Aerogel:
 - Well known as a RICH radiator, e.g. from ARICH at Belle II
 - $n = 1.01-1.10 \implies \theta_c = 141-430 \text{ mrad}$, suitable at low momentum
 - Very low thermal conductivity
 - Suitable to separate gas from detector, which must be cooled
 - Cherenkov photons come for "free" and are focused by the same mirror
 - Drawback: Some loss of photons from scattering

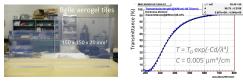

Figure 7: Belle aerogel tiles (left) and aerogel transmission function (right).

Photon hits

ARC

Optimisation of ARC layout

- The following procedure is used to evaluate the ARC performance:
 - **(**) Generate straight particle track from IP and trace it through ARC
 - 2 Generate Cherenkov photons from gas radiator
 - Track photons through the optics and to detector
 - Reconstruct Cherenkov angles and calculate standard deviation
- Three sources of uncertainty are considered:
 - Emission point uncertainty: Emission point is assumed to be the mid-point of the track inside the gaseous radiator
 - Chromatic dispersion uncertainty: Spread in Cherenkov angle due to wavelength dependence on refractive index
 - Ixel size: Will be chosen so that it does not limit the performance

Minimise the Cherenkov angle uncertainty:

$$\Delta heta = rac{1}{\sqrt{N}} imes rac{1}{1-N} imes \sum_{i=0}^{N-1} (heta - ar{ heta})^2$$

Examples of photon tracking through optimised layout

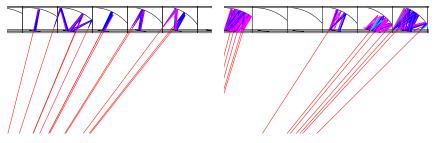

Figure 10: Tracking of photons from gas radiator (left) and aerogel radiator (right) through the ARC optics

- Parameters that are optimised:
 - Mirror curvature
 - Mirror vertical and horizontal position
 - Detector horizontal position and tilt

Cherenkov angle uncertainty for gas radiator

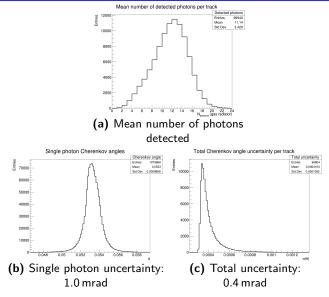

Figure 11: Gas radiator performance averaged over all barrel cells

Cherenkov angle uncertainty for aerogel radiator

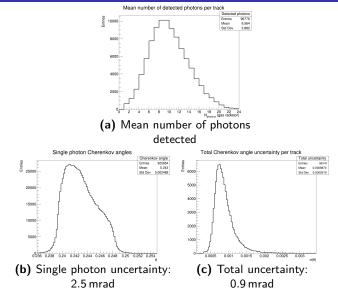

Figure 12: Aerogel radiator performance averaged over all barrel cells

Performance of optimised ARC

Kaon-pion separation significance in ARC barrel

Kaon-proton separation significance in ARC barrel

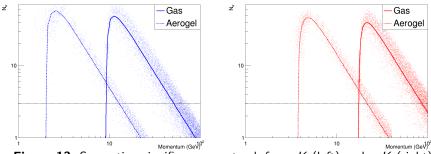

Figure 13: Separation significance per track for π -K (left) and p-K (right)

- Gas (aerogel) provides over 3σ pion-kaon separation in the range 10-50 GeV (2-10 GeV)
 - Improved from earlier studies due to gaining some space for more radiator by no longer pressurising, as well as optimisation of the layout
 - Effect of magnetic field not yet included in these studies
- Combined, the aerogel and gas ensure excellent PID performance over the whole range of interest to flavour physics

Summary and next steps

- ARC is a low mass and compact cellular PID detector designed to occupy minimum space (20 cm in the radial dimension) in a 4π detector at an e^+e^- collider such as FCC-ee
- We have developed an optimised layout that should achieve a 3σ kaon-pion separation in the range 2-50 GeV
 - Our studies focus mainly on flavour physics at the Z-pole
- ARC will allow us to fully exploit the full range of flavour physics potential at future e^+e^- colliders
 - Will enhance the capabilities in Higgs, WW and top physics
- Next steps will include completing the optimisation, including magnetic field effects, and R&D on photodetectors

Thanks for your attention!

Units of radiation	length	X/	X_0
--------------------	--------	----	-------

Detector component	Pressurised	Non-pressurised
Vessel walls	5%	1%
Photosensor array/electronics	1%	1%
Cooling plate (3 mm CF)	1%	1%
Aerogel ($n = 1.03$)	1%	0.5%
C_4F_{10} gas	1%	0.5%
Focusing mirror	1%	1%
Total	10%	5%

- $f(\vec{x})$ is not easily to calculate analytically
- Approximate by simulating a large number of charged tracks
- Finite number of photons $\implies f(\vec{x})$ is not differentiable
 - Cannot be minimised using conventional methods (Minuit, etc)
- I have experimented with a new type of minimisation algorithms: Stochastic optimisation
 - Differential evolution
 - Start with a population of possible solutions, form new solutions by combining (mutating) existing solutions
 - Advantage: Doesn't require initial guess, robust against functions that a not continuous, noisy, change over time, etc
 - Disadvantage: No way to tell if optimal solution has been found, so it requires many iterations
