## Imperial College London

# IC plans for CP measurements in Run 3

Daniel Winterbottom <u>d.winterbottom15@imperial.ac.uk</u>

#### **Person power**

- Senior: David, Sasha
- Postdoc: Me
- PhD students:
  - Klitos (until March 25)
  - Would plan to get another PhD student overlapping with Klitos to take us to the end of the full Run 3 analysis
- MSc students:
  - Qintong (until Sep 22)
  - Possibility to get ~ 1 MSc student per year (masters projects related to HEP+ML)

### General aims / plans

- Produce measurement of CP in HTT decays using Run 3 + Run 2 data
  - New analysis on Run 3 data + either re-analysis of Run 2 or combination with HIG-20-006
- Move analysis methods more towards polarimetric method for other channels
  - At least for a1 decays, and perhaps for other decay modes (i.e including additional information/ constraints e.g MET)
- Extract CP information in ggH production and decay simultaneously
  - Need appropriate MC samples for this
- Improve signal vs background separation
- Improve tau decay mode identification and reconstruction of  $\pi 0$ 
  - E.g Something similar to this interesting EGM paper about merged photons EGM-20-001

26/04

#### Moving to polarimetric vector method

- Tried very simple procedure to use polarimetric vector method for a1's in other channels
- We take the tau direction from SV-PV (+ a rotation for cases where GJ angle is > maximum)
- Absolute value of tau momentum from SV-fit
- Despite procedure being simple a significant improvement is observed in the separation e.f for ρ-a1 channel

#### Moving to polarimetric vector method

- Tried very simple procedure to use polarimetric vector method for a1's in other channels
- We take the tau direction from SV-PV (+ a rotation for cases where GJ angle is > maximum)
- Absolute value of tau momentum from SV-fit
- Despite procedure being simple a significant improvement is observed in the separation e.f for ρ-a1 channel

#### Improvements to significances

- Checked improvement in tt channel from using the police method for the a1's
- Significance with old method =  $1.87\sigma$
- Significance with new method =  $2.06\sigma$
- Gives ~ 8% gain overall
- Could do better if we can use finer binning for the a1 channels (we use 4 bins compared to 10 for most sensitive channels)
- Could also improve these channels further by rejecting more fake background events in SR

### Improving tau decay mode identification and reconstruction of $\pi 0$

- Check how much improving angular resolution on pi0's will improve the CP-even vs CP-odd sensitivity
- Shift reconstructed pi0  $\phi$  and  $\eta$  closer to generator values
- $\phi' = (\phi_{gen} \phi)^* \text{shift} + \phi$ ;  $\eta' = (\eta_{gen} \eta)^* \text{shift} + \eta$
- Current resolution: shift=0, perfect reconstruction: shift=1

### Improving tau decay mode identification and reconstruction of $\pi 0$

- Check how much improving angular resolution on pi0's will improve the CP-even vs CP-odd sensitivity
- Shift reconstructed pi0  $\phi$  and  $\eta$  closer to generator values
- $\phi' = (\phi_{gen} \phi)^* shift + \phi; \eta' = (\eta_{gen} \eta)^* shift + \eta$
- Current resolution: shift=0, perfect reconstruction: shift=1

d.winterbottom@imperial.ac.uk

- From VBF MC sample of ρ decays our situation is closest to "Shower merged" scenario
- In the paper this is arguably the category where the largest improvement is observed

## Other improvements of using ML for pi0s

- We will likely recover some events where HPS does not identify any pi0 (~20% of ρ decays fall into this category)
- We will likely be able to improve the decay mode identification accuracy
- We may be able to resolve 2 pi0's in some cases for a1 decays and may be able to define a more sensitive CP-observable in this case

**Separation between gammas**

#### MC samples

- VBF+VH: Plan to use same setup as for Run 2 but will m make requests for Run 2 UL samples + eventually Run 3
- For ggH if we want to measure CP in production and decay need samples that can model production side
  - For HIG-20-007 we used Madgraph for this but large number of negative weights made this tricky (~9x as many events needed for NLO vs LO)
  - However now possible to use a Madgraph+POWHEG interface (<u>https://arxiv.org/abs/2008.06364</u>) to reduce the number of negative weights (now need only ~ 1.5x as many events compared to LO)
  - Already tested this for a few events see right
  - Update: preparing gridpack for Run2 SM case, generation seems very slow when using gridpacks compared to using standalone code - need to understand why
