

# DETECTORS FOR HIGH ENERGY PHYSICS

Part 4

Ingrid-Maria Gregor  
DESY/Universität Bonn  
Summerstudents 2022  
08.08.2022

## IV.B GAS-DETECTORS

# ANOTHER CLASSIC: IONISATION CHAMBER

- Passage of particles creates within the gas volume electron-ion pair (ionisation)
- Electrons are accelerated in a strong electric field -> amplification
- The signal is proportional to the original deposited charge or is saturated (depending on the voltage)

Variation of ion pair charge with applied voltage

# PROPORTIONAL CHAMBER

## Disadvantage of planar design:

- E uniform and  $\perp$  to the electrodes:
- amount of ionisation produced proportional to path length and to position where the ionisation occurs  
-> not proportional to energy

Problem solved using **Cylindrical proportional counter:**

- Single anode wire in a cylindrical cathode
- $E \sim 1/r$ : weak field far from the wire electrons/ions drift in the volume multiplication occurs only near the anode

# TIME DEVELOPMENT OF THE SIGNAL

- The signal on the electrodes is **induced by the movement of ions and electrons as they drift towards the cathode and anode** respectively rather than by collection of charge at the electrodes
- The electrons are collected very fast (in  $\sim 1\text{ns}$ ) while drifting over the few mm drift distance, while the positive ions drift slowly towards the cathode.
- It is the **ion drift** which determines the time development and the size of the induced signal. The electrons induce very little signal.

# MULTI-WIRE-PROPORTIONAL CHAMBER

Schematic setup:

Parameters:

$d = 2 - 4 \text{ mm}$

$r_w = 20 - 25 \text{ } \mu\text{m}$

$L = 3 - 6 \text{ mm}$

$U_0 = \text{several kV}$

Total area:  $O(m^2)$

Features:

Tracking of charged particles

Some PID capabilities via  $dE/dx$

Large area coverage

High rate capabilities

particle track

# SIGNAL IN MWPC

## Signal generation:

- Electrons drift to closest wire
- Gas amplification near wire → avalanche Signal generation due to electrons and **mainly slow ions**

- Only information about closest wire  
→  $\sigma_x = d/\sqrt{12}$   
[Only one dimension information]
- **Possible improvements:** - segmented cathode
  - 2-dim.: use 2 MWPCs with different orientation
  - 3-dim.: several layers of such X-Y-MWPC combinations [tracking]

# ADDING TIME: DRIFT CHAMBER

- Alternative way to obtain spatial information: **measure the electrons drift time:**
  - time measurement started by an external (fast) detector, i.e. scintillator counter
  - electrons drift to the anode (sense wire), in the field created by the cathodes with constant velocity
  - the electron arrival at the anode stops the time measurement
  - one-coordinate measurement:

Wire chamber CDF (@Tevatron)

$$x = \int_0^{t_D} v_D dt$$

velocity  $\vec{v}_D = \mu_{\pm} |\vec{E}|$   
 $\mu_{+}$  mobility

# WIRE STRINGING IN PROGRESS

# END PLATE CLOSE UP

# TRANSITION RADIATION

## Transition Radiation

- Produced by relativistic charged particles when they cross the interface of two media of different refraction indices
- Can be explained by re-arrangement of electric field
- Energy loss at a boundary is proportional to the relativistic gamma factor.
  - A significant amount of transition radiation is produced for a gamma greater than 1000.
  - Gamma factor of protons is, up to a momentum of 5GeV, still in the order of 10.
  - Positron's gamma is greater than 1000 starting at 0.5GeV momentum.

$$I \propto m\gamma = \frac{1}{\sqrt{(1 - \beta^2)}}$$

=> particle identification

# TRANSITION RADIATION TRACKER

## Signal formation

- charged particles ionize the gas
- electrons drift towards the wire
- gas amplification avalanche
- first arrival determines drift time

## Signal readout

- signal gets amplified
- sampled in 24 time bins of 3.12 ns
- each time bin compared against threshold ( $\approx 300$  eV): 24-bit pattern
- buffered in 6- $\mu$ s readout pipeline
- passed on to central ATLAS DAQ

allows self supporting structures

# A STACK OF STRAWS

Endcap (~32000 straws)  
radial from beam axis

ATLAS Inner Detector

straws

Barrel (~10000 straws)  
parallel to beam axis

# THE FIRST ATLAS TRT END-CAP (3 AUG 2005)

# TPC- TIME PROJECTION CHAMBER: 3D

- Combination of the the 2D track information and the time results in a real 3D point

- Readout of the anode usually with multi wire projection chambers
- Nowadays new developments under way.

Pic: DESY

Pic: ALICE Collaboration

# NEWER DEVELOPMENTS

- Largely improved spacial resolution and higher particle rates:

## Micro-Pattern Gas Detectors

- a number of developments were started, some with a lot of problems
- two technologies are currently the most successful: GEMs and MicroMegas
- MicroMegas: Avalanche amplification in a small gap

# NEWER DEVELOPMENTS

- GEM: Gas Electron Multiplier: Gas amplification in small holes in a special foil

Charge collection on two separate levels: 2D structure possible: separation of amplification and read out

Both technologies, MicroMegas and GEMs are used in experiments. Typical spatial resolution:  $\sim 70 \mu\text{m}$

# MPGDs AS NEXT GENERATION DETECTOR

- Combination of gas detectors and Silicon
  - Integration of MPGDs with pixel read out chips

- Amplification and read out made of silicon

## Advantages of gas detectors:

- Low radiation length
- Gas can be replaced regularly: Reduction of radiation damages!

# SUMMARY TRACKING DETECTORS

- Tracking detectors are playing an important role in HEP since the late 50ties
- Starting with bubble chamber the development of tracking detectors was rather rapidly
- Modern gas detectors and silicon trackers play an equal important role in HEP
- LHC silicon trackers are used for the inner systems while gas detector dominate the outer tracking systems (muon detectors)
- The technologies are rapidly evolving giving hope to have really fancy detectors for example for the future LC

# MUON SPECTROMETER

**Muon-Detectors:** Identification and precise momentum measurement of muons outside of the magnet

The dashed tracks are invisible to the detector

# MUON DETECTORS

- Identification and precise momentum measurement of muons outside of the magnet
- Benchmark design for muon detectors: momentum measurement better than 10% up to 1 TeV.
  - $\Delta p_T/p_T \approx 1/BL^2$
- Typical track in Muon System has  $\approx 20$  hits
- A muon tracks can be:
  - “standalone” purely based on MS
  - “combined” btw MS and ID
- The standalone capability can be crucial at high luminosity when ID is “very crowded”
- The momentum measurement is dominated by
  - ID @ low  $p_T$
  - MS @ high  $p_T$

# MUON SYSTEMS

# PRECISION CHAMBERS

## 1) Monitored Drift Tubes (MDT)

Drift Tube

High-pressure drift tubes  
 $\sigma(R) \approx 100 \mu\text{m}$ ,  $T_{\text{drift}} \approx 700 \text{ns}$

- Gas-filled drift tubes with central wire
- Signal read out on both ends
- Spatial resolution increased by recording drift time.
- Three concentric barrel layers plus end-cap ( $\eta=2.7$ ).
- Total of 355000 tubes.

## 2) Cathode Strip Chambers

Operation in high rate environment  
 $\sigma(R) \approx 60 \mu\text{m}$ ,  $T_{\text{drift}} \approx 20 \text{ns}$

- Array of anode wires crossed with copper cathode strips within gas volume.
- Short drift distances.
- Suited for high  $\eta$

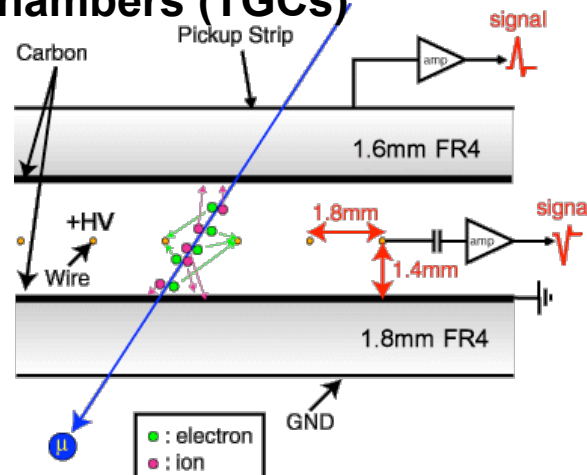

# TRIGGER CHAMBERS

## 1) Resistive Plate Chambers (RPCs)

- Robust detector with up to 5ns time resolution
- Charge carriers drift towards anode and get multiplied by electric field (avalanche).
- Applied high voltage at parallel plate electrodes leads to uniform electric field in the gas gap.
- The propagation of the growing number of charges induces a signal on a read out electrode.
- In ATLAS the Barrel is equipped with RPCs.

## 2) Thin Gap Chambers (TGCs)

- Derivative of MWPCs
- Operation in saturated mode. Signal amplitude limited by the resistivity of the graphite layer
- In ATLAS the End-cap is equipped with TGCs.

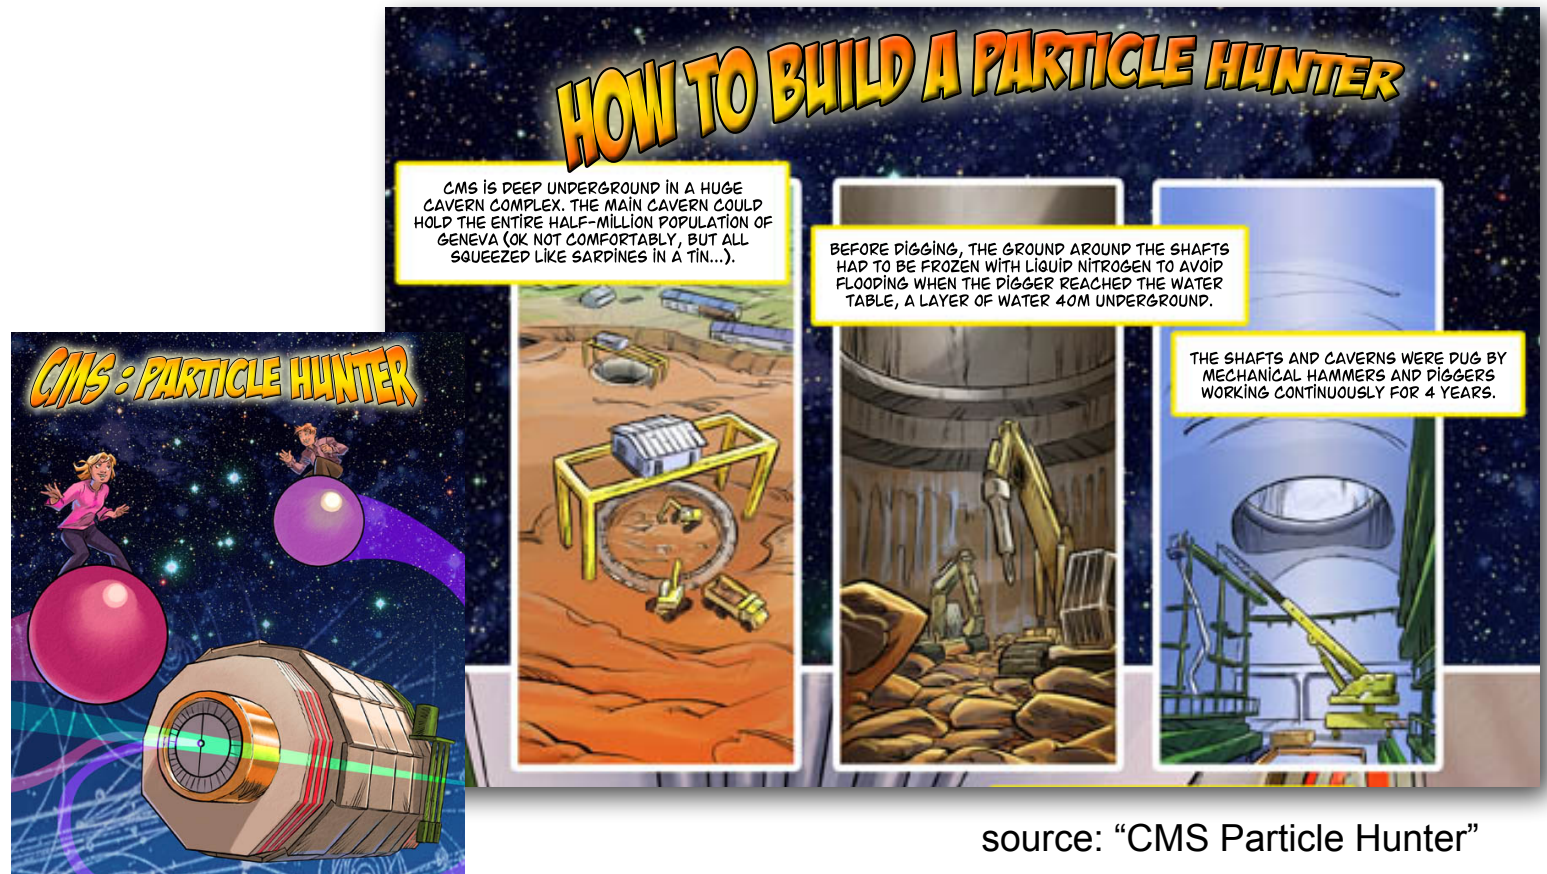

## **V. REAL LIFE EXAMPLES**

### **BUILDING AN EXPERIMENT (EXAMPLE LHC)**

# CURRENT HEP DETECTOR R&D

- Detector development is always an important topic in high energy physics
- Technical demands are constantly increasing due to new challenges in particle physics
  - higher occupancy, smaller feature size, larger trigger rates, radiation level, .....
- New HEP detector projects are planned for
  - Detector upgrades during different LHC phases up to HL-LHC (ATLAS, CMS, ALICE, LHCb)
  - Detector R&D for a future linear collider (ILC and CLIC)
  - Belle II (construction phase ongoing)
  - PANDA and CBM @Fair
  - .....

source: "CMS Particle Hunter"

# HOW TO DO A PARTICLE PHYSICS EXPERIMENT

- Ingredients needed:

- particle source
- accelerator and aiming device
- detector
- trigger
- recording devices

- Recipe:

- get particles (e.g. protons, antiprotons, electrons, ...)
- accelerate them
- collide them
- observe and record the events
- analyse and interpret the data
- many people to:
  - design, build, test, operate accelerate
  - design, build, test, calibrate, operate, understand the detector
  - analyse data

● lots of money to pay all this ....

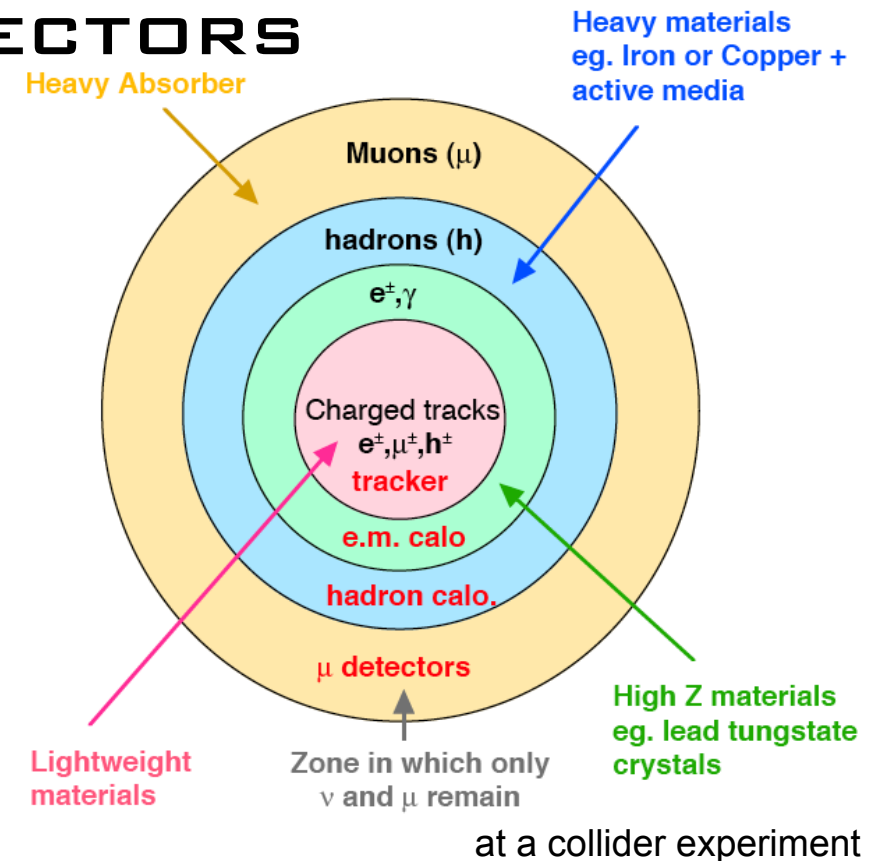

typical HERA collaboration: ~400 people  
LHC collaborations: >2000 people

Pic: DESY

# CONCEPTUAL DESIGN OF HEP DETECTORS

- Need detailed understanding of
  - processes you want to measure (“physics case”)
  - signatures, particle energies and rates to be expected
  - background conditions
- Decide on magnetic field
  - only around tracker?
  - extending further ?
- Calorimeter choice
  - define geometry (nuclear reaction length,  $X_0$ )
  - type of calorimeter (can be mixed)
  - choice of material depends also on funds

- Tracker
  - technology choice (gas and/or Si?)
  - number of layers, coverage, ...
  - pitch, thickness, ....
  - also here money plays a role

Detailed Monte Carlo Simulations need to guide the design process all the time !!

# A MAGNET FOR A LHC EXPERIMENT

## ● Wish list

- big: long lever arm for tracking
- high magnetic field
- low material budget or outside detector (radiation length, absorption)
- serve as mechanical support
- reliable operation
- cheap
- ....

## ● ATLAS decision

- achieve a high-precision stand-alone momentum measurement of muons
- need magnetic field in muon region -> large radius magnet

## ● CMS decision

- single magnet with the highest possible field in inner tracker (momentum resolution)
- muon detector outside of magnet

Eierlegende Wollmilchsau

www.positoons.de

# MAGNET-CONCEPTS: ATLAS -> TOROID

- Central toroid field outside the calorimeter within muon-system: <4 T
  - Closed field, no yoke
  - Complex field
- Thin-walled 2 T Solenoid-field for trackers integrated into the cryostat of the ECAL barrel

- + field always perpendicular to  $\vec{p}$
- + relative large field over large volume
- non uniform field
- complex structure

# MAGNET-CONCEPTS: CMS -> SOLENOID

- super conducting, 3.8 T field inside coil
- weaker opposite field in return yoke (2T)
- encloses trackers and calorimeter
- 13 m long, inner radius 5.9 m,  $I = 20$  kA, weight of coil: 220 t

- + large homogeneous field inside coil
- + weak opposite field in return yoke
- size limited (cost)
- relative high material budget

# WHAT IS A TRIGGER ?

- Collisions every 25 ns with many simultaneous interactions
- A lot of information stored in the detectors - we need all information
- Electronics too slow to read out all information for **every** collision
- But: a lot of the interactions are very well known - we only want rare events
- “Trigger” is a system that uses simple criteria to rapidly decide which events to keep when only a small fraction of the total can be recorded.

- Want to know the information of green cars
  - number of passengers
  - speed
  - weight
  - .....
- Trigger = system detecting the color and initiating the information transfer all information

# EXPERIMENTAL CONSTRAINTS

Different experiments have very different trigger requirements due to operating environments

- Timing structure of beam
- Rate of producing physics signals of interest and rate of producing backgrounds
- **Cosmic Ray Experiments**
  - no periodic timing structure, background/calibration source for many other experiments
- **Fixed Target Experiments**
  - close spacing between bunches in train which comes at low rep rate ( $\sim$ Hz)
    - backgrounds from un-desirable spray from target
    - cosmics are particularly a background for neutrino beams
- **e<sup>+</sup>e<sup>-</sup> colliders**
  - very close bunch spacing (few nsec), beam gas and beam wall collisions
- **ep collider**
  - short bunch spacing (96ns), beam gas backgrounds
- **pp/ppbar collider**
  - modest bunch spacing (25-400ns), low produced soft QCD

## V. REAL LIFE EXAMPLES AND WHAT CAN GO WRONG ...

# PROBLEMS WITH WIRE BONDS (CDF, DO)

- Very important connection technology for tracking detectors: wire bonds:
  - 17-20  $\mu\text{m}$  small wire connection  $\rightarrow$  terrible sensitive ....
- During test pulse operation, Lorentz force on bonding wires (perpendicular to magnetic field) caused resonances ...

...breaks wire bonds  
between detector  
and read out.

during running

# MORE WIRE BOND WRECKAGE

- Quality of wires is tested by pull tests (measured in g)
- During CMS strip tracker production quality assurance applied before and after transport (via plane)
- Wire bonds were weaker after flight
- Random 3.4 g NASA vibration test causes similar damage
- Problem observed during production -> improved by adding a glue layer
- No further problems during production

**during production**

# UNEXPECTED PROBLEMS ATLAS BARREL TRT

- Gas mixture: 70% Xe + 20 CF<sub>4</sub> + 10% CO<sub>2</sub>
- Observed: **destruction of glass joint between long wires after 0.3 - 0.4 integrated charge** (very soon after start up)

At high irradiation C<sub>4</sub>F turns partially into HF, F<sub>2</sub> (hydrofluoric acid)  
-> attaches Si-based materials in the detector

- Changed gas mixture, after ~10 years of R&D with old mixture

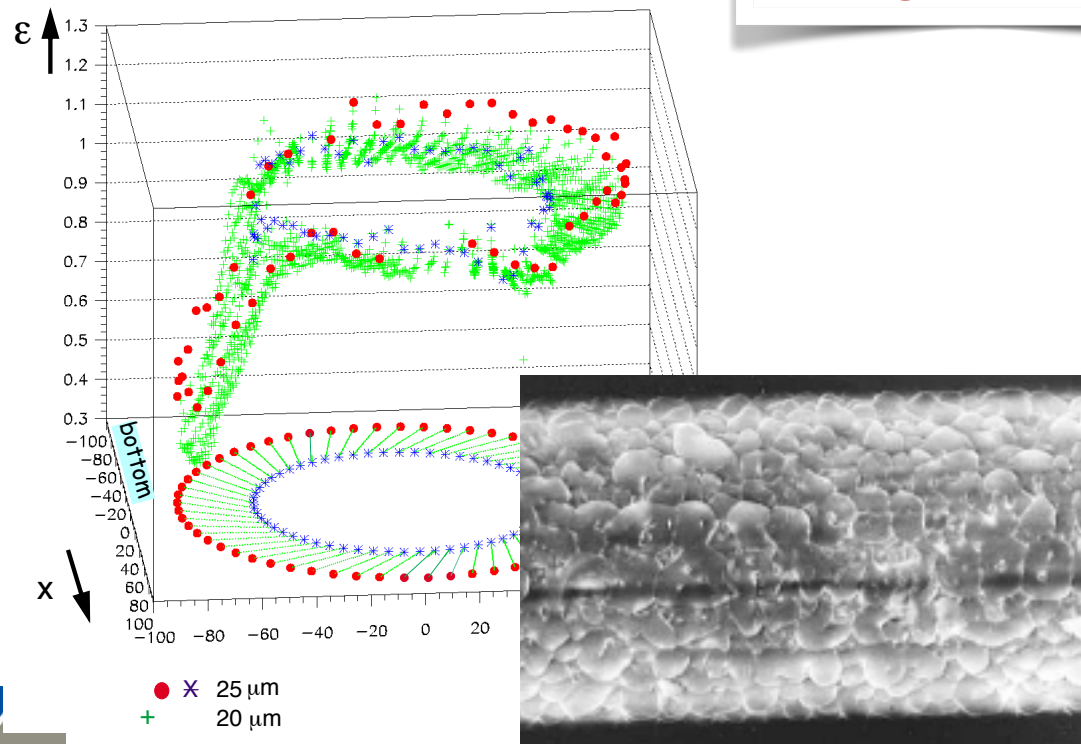

**during production**

# WIRES H1 CENTRAL JET CHAMBER

- Outer tracker of H1 -> broken wires in CJC1
- Observation / possible reason:
  - remnants from gold plating process lead to complex chemical reactions
- New design of crimp tube: jewels • better quality control

during production

- Sense Wire Deposits in CJC2
- Observation / possible reason:
  - $y$  dependence implies most likely gas impurity
- Consequences:
  - sense wires replaced
  - changes in gas distribution
  - increased gas flow

during running

# WATER DAMAGE IN TRACKER ...

- H1@HERA FST in 2004
- Imperfect crimp + hardening of plastic => water leak
- Water condensation => damage
- Tracker segment had to be rebuilt

during running

# IMPLODED PMTs @ SUPERKAMIOKANDE

- On November 2001 a PMT imploded creating a shock wave destroying about 7700 of other PMTs (costing about \$3000 each)
- Chain reaction: a the **shock wave** from the concussion of each imploding tube cracked its neighbours.
- Detector was partially restored by redistributing the photomultiplier tubes which did not implode.

**during commissioning**

# SUMMARY

- I could only give a **glimpse** at the wealth of particle detectors. More detectors are around: medical application, synchrotron radiation experiments, astro particle physics, ...
- All detectors base on similar principles
  - Particle detection is indirectly by (electromagnetic) interactions with the detector material
- Large detectors are typically build up in layers (onion concept):
  - Inner tracking: momentum measurement using a B-field
  - Outside calorimeter: energy measurement by total absorption
- Many different technologies:
  - Gas- and semiconductors (light material) for tracking
  - Sampling and Homogeneous calorimeters for energy measurement
- Similar methods are used in astro particle physics
- **Always looking for new ideas and technologies!**
