Plan of the presentation

1. Anisotropy in 2 hits events
 - 1.1 Motivation
 - 1.2 GaAs vs Calice
 - 1.3 Method
 - 1.4 Results
 - 1.5 Close look for amplitude distribution in 2 hits events
 - 1.6 Separation of 2 hits events types
 - 1.7 Anisotropy after separation

Motivation

We were trying to understand nature of bump below Landau-Gauss MPV in GaAs sensors (not seen in Calice sensors).

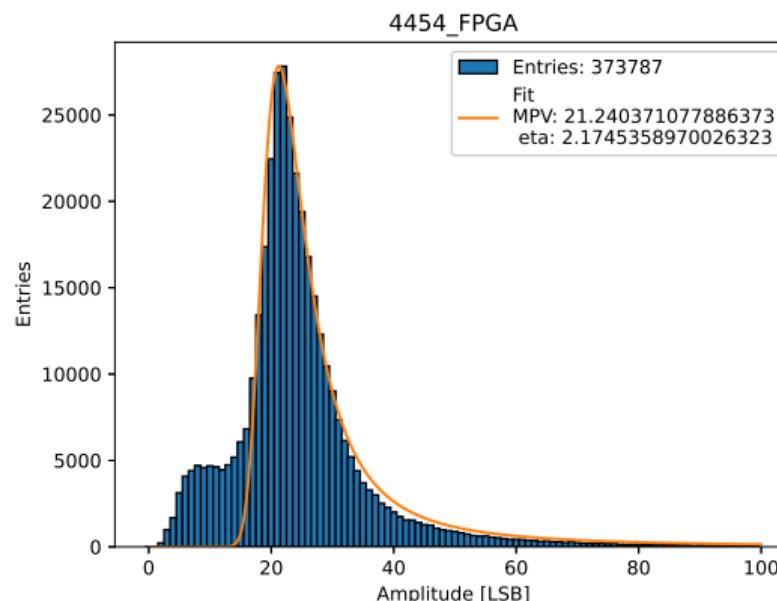

Fig. 1: Distribution of hits amplitude in Anton 1 sensor

GaAs vs Calice

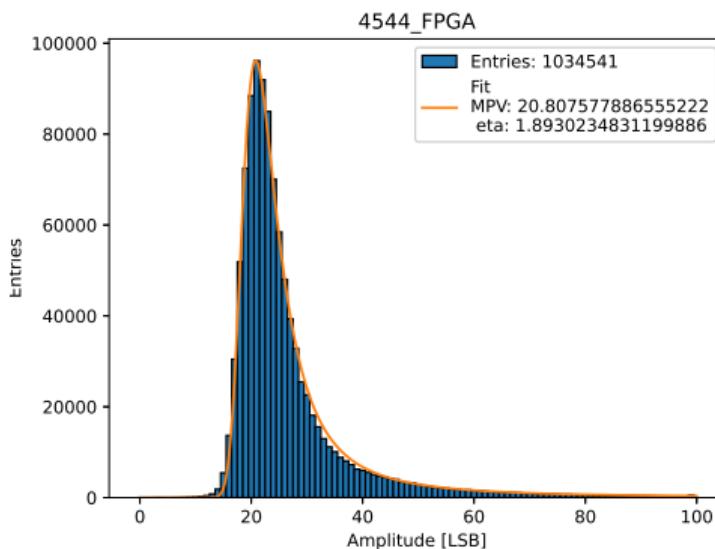

Fig. 2: Distribution of hits amplitude in Calice 74 sensor

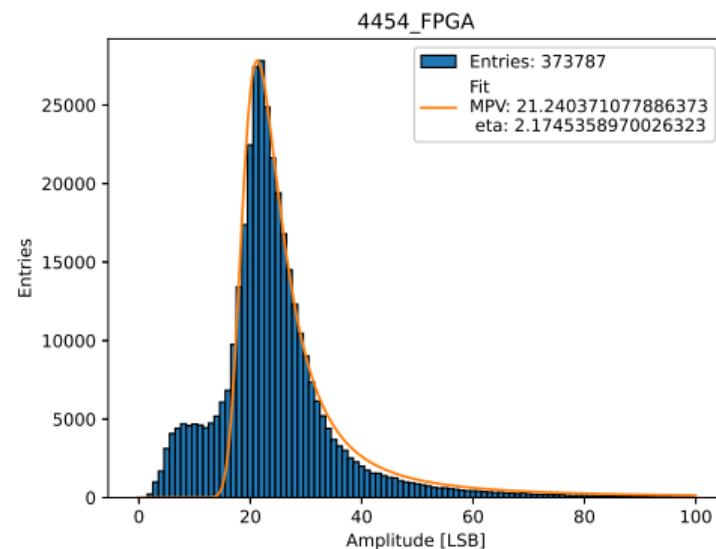

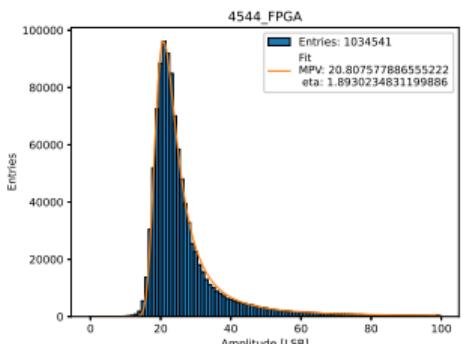

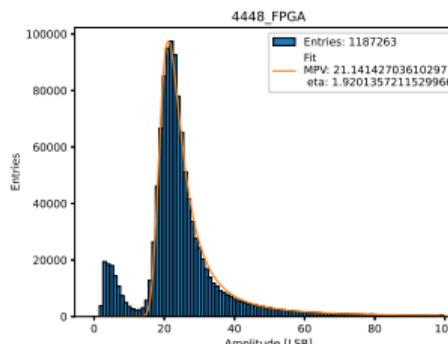

Fig. 3: Distribution of hits amplitude in Anton 1 sensor

GaAs vs Calice

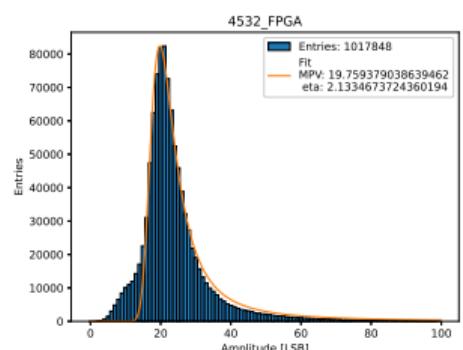

In Anton 1 and Yan 1 sensors there are bumps below Landau-Gauss MPV (in Yan 1 much less than Anton 1).

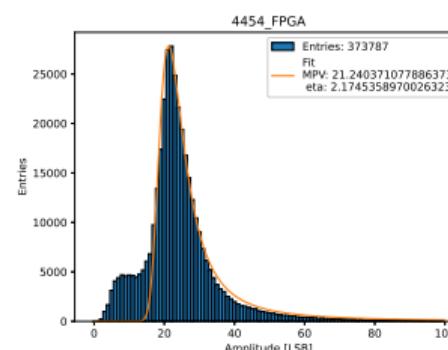

(a) Calice 74

(b) Calice 75

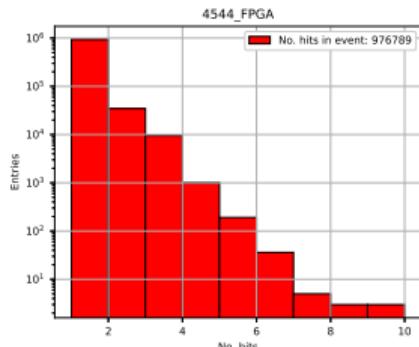

(c) Yan 1

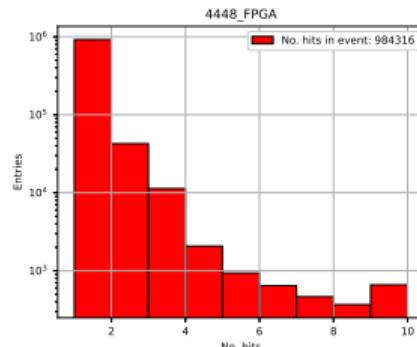

(d) Anton 1

GaAs vs Calice

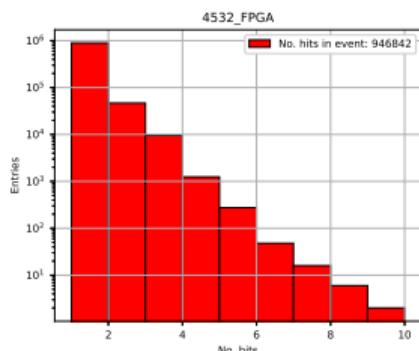

In Anton 1 and Yan
1 sensors number of
hits in event
distribution
decreases a little bit
slower than in Calice
sensors.

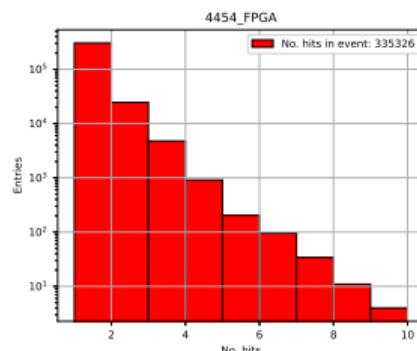

(a) Calice 74

(b) Calice 75

(c) Yan 1

(d) Anton 1

GaAs vs Calice

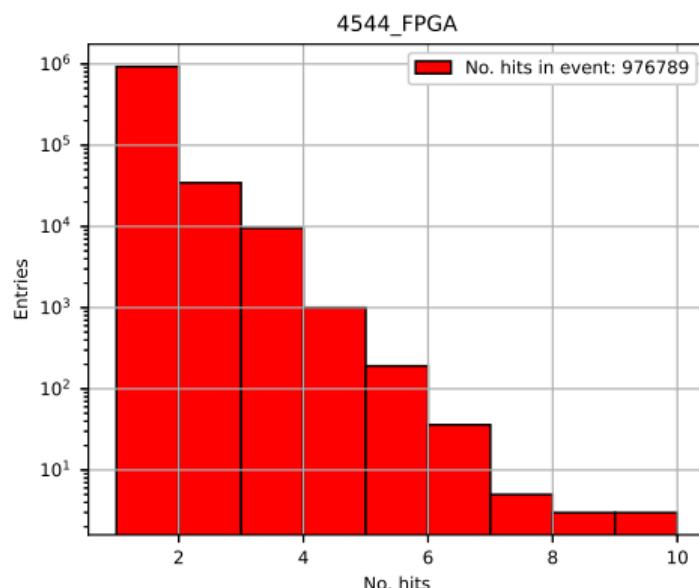

Fig. 6: Calice 74 run 4544

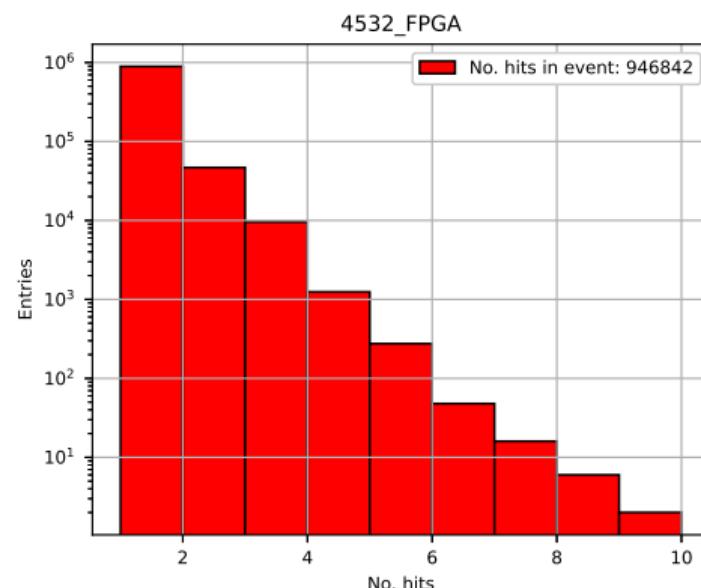

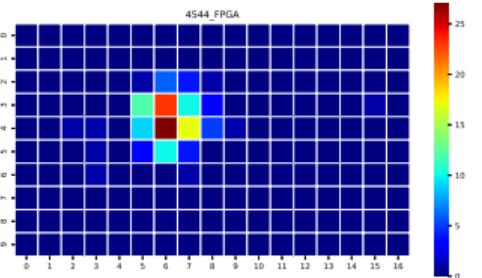

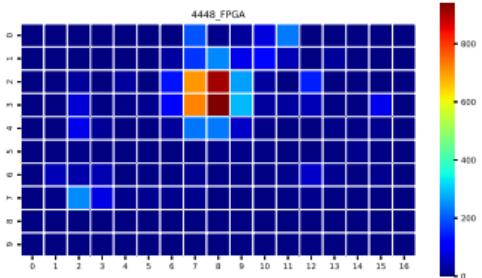

Fig. 7: Yan 1 run 4532

GaAs vs Calice

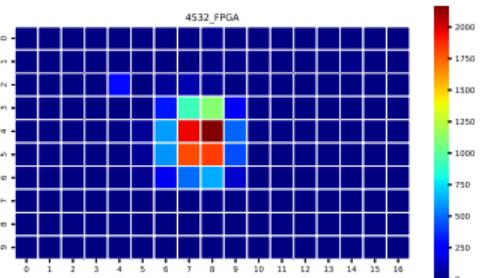

Spatial distribution of hits from 2-hit events doesn't shows difference between this four sensors.

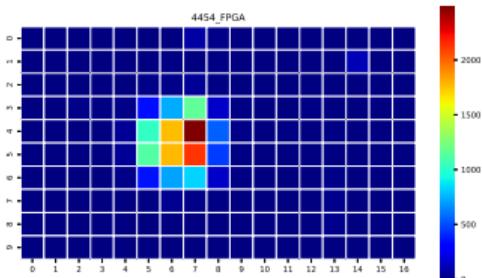

(a) Calice 74

(b) Calice 75

(c) Yan 1

(d) Anton 1

Analysis of geometry

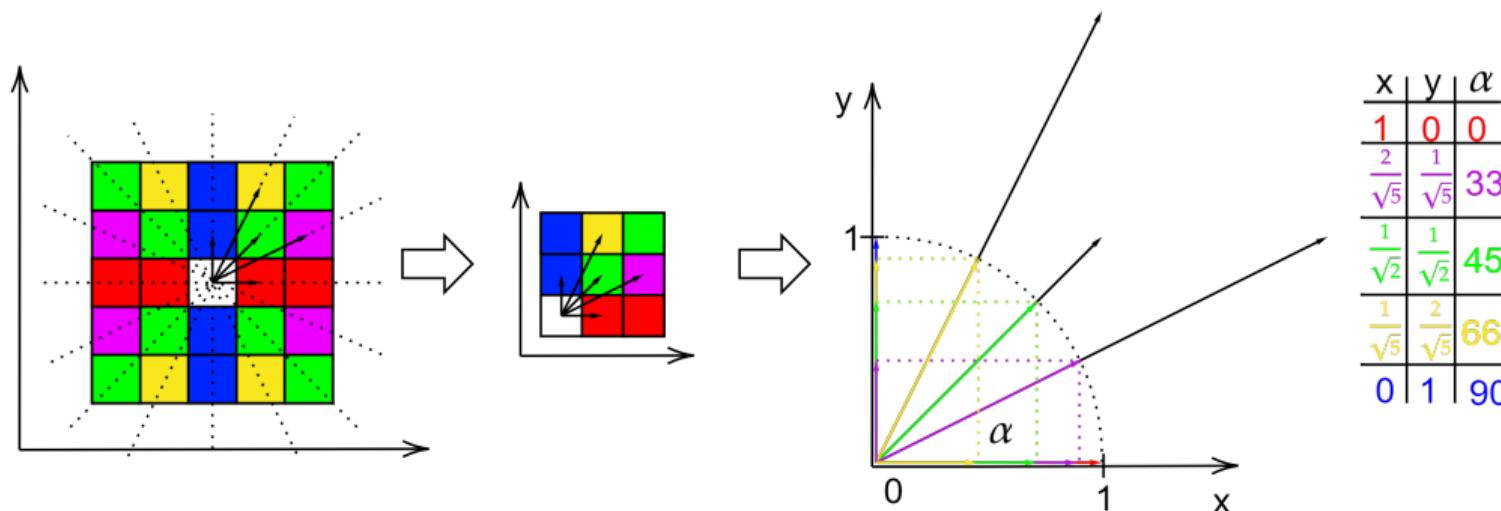

Fig. 9: Geometry explanation

Analysis of spatial configurations of 2-hit events

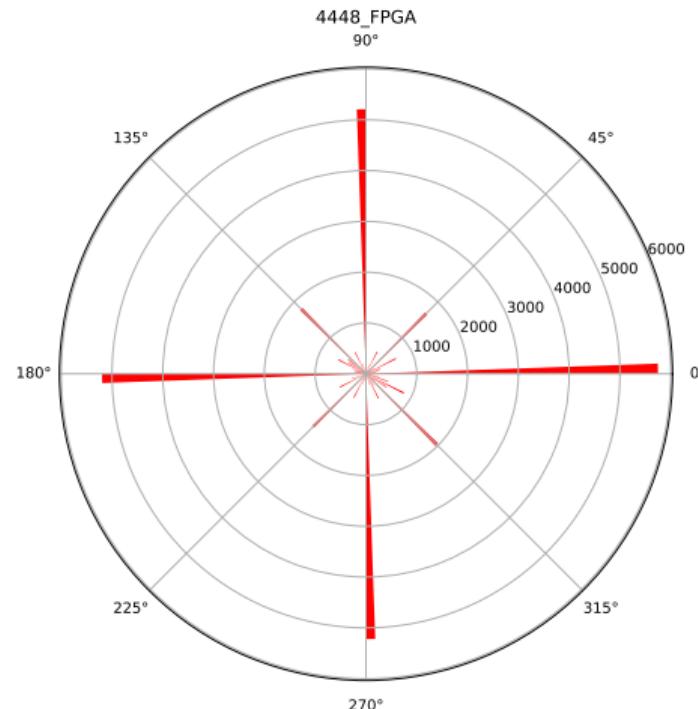

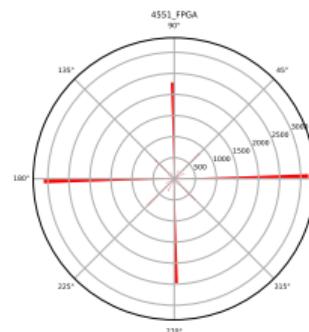

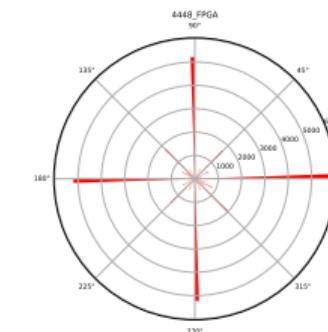

Fig. 13: Calice 75 run 4448

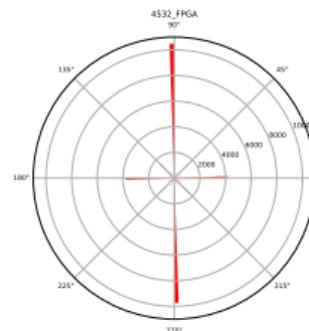

Anisotropy

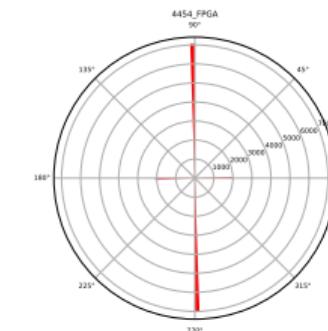

(a) Calice 74

(b) Calice 75

(c) Yan 1

(d) Anton 1

In GaAs sensors, we can clearly see the anisotropy on the y axis - axis of trace direction.

Sensors

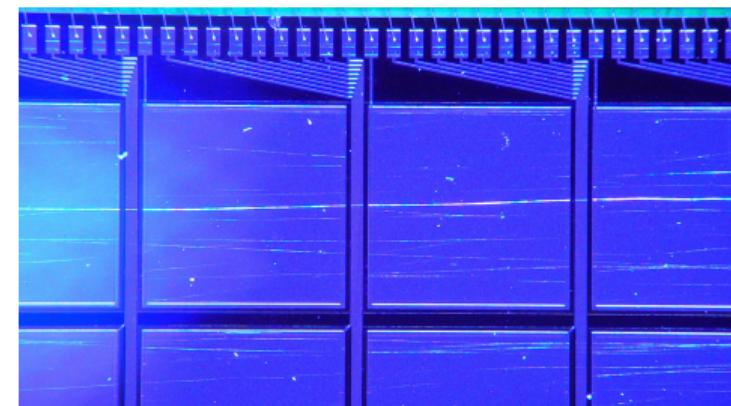

Fig. 16: Anton 1

Anisotropy

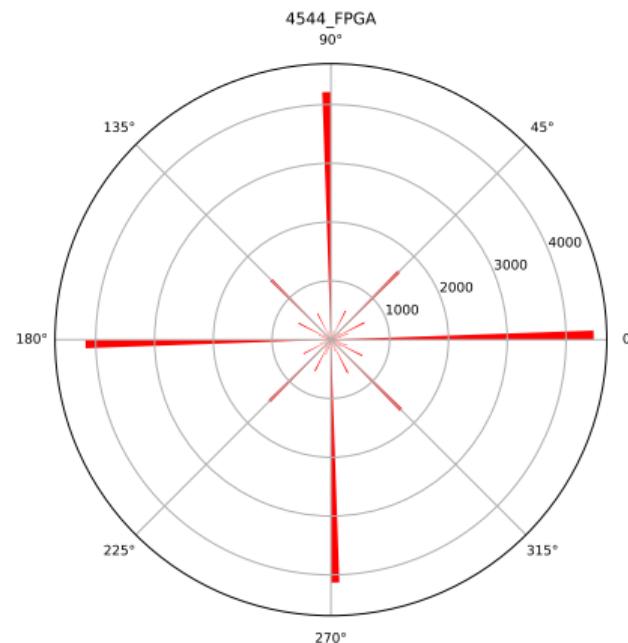

Fig. 17: Calice 74 run 4544

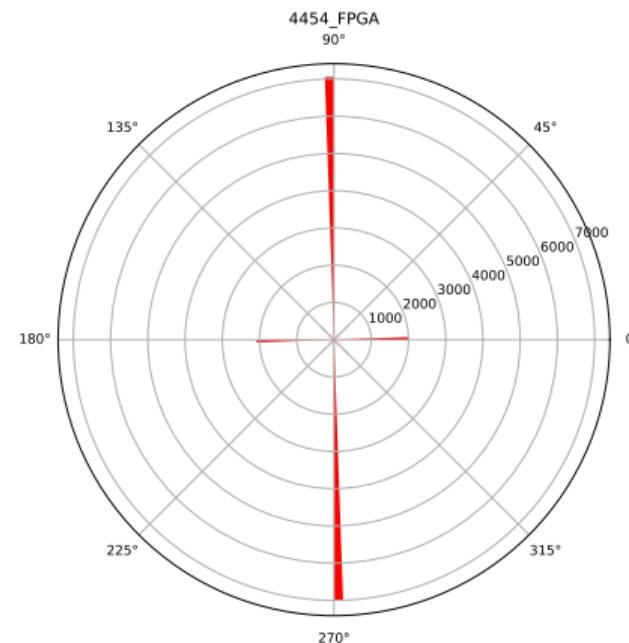

Fig. 18: Anton 1 run 4454

Amplitude of 2 hits events

A fraction of the distribution of sum amplitudes in event comes from two different particles. Can we explain why there are so many ($3 \pm 1\%$) of them?

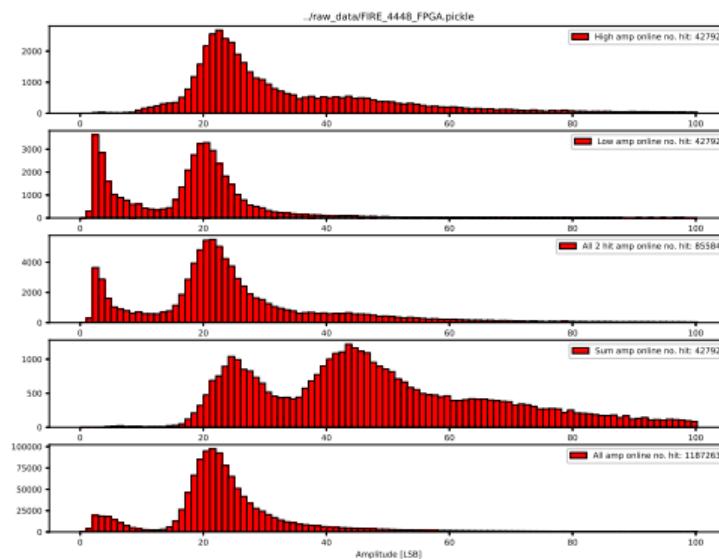

Fig. 19: Calice 75 run 4448

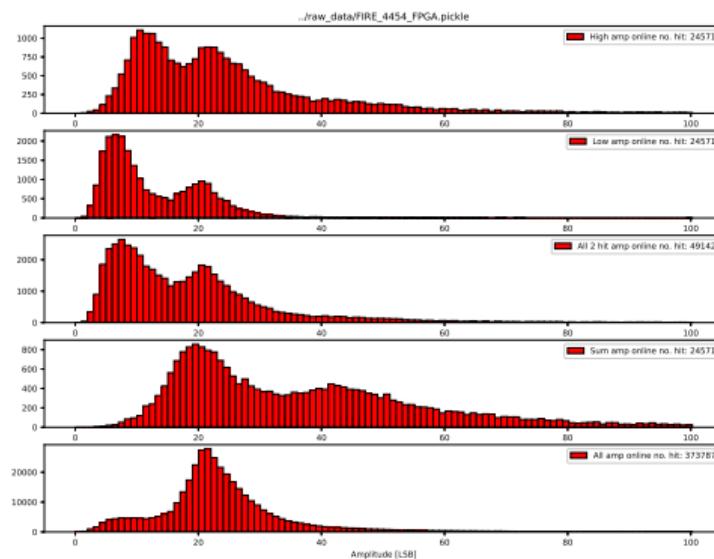

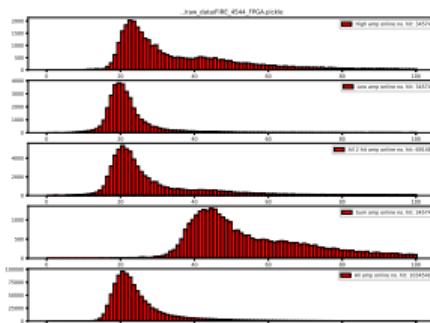

Fig. 20: Anton 1 run 4454

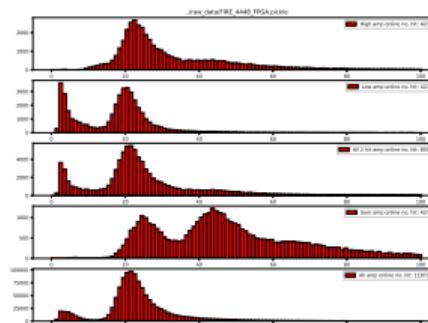

Amplitude of 2 hits events

In Anton 1 and Yan 1 sensors there are clearly visible differences in sum of amplitudes in event. Does big fraction of one particle 2-hit events come from:

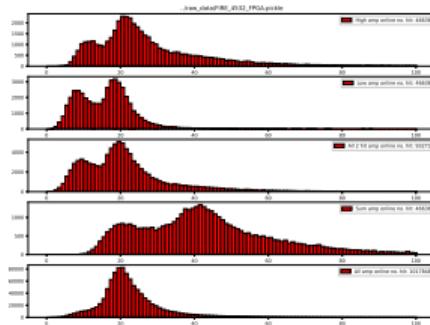

- ▶ charge sharing?
- ▶ cross-talk?

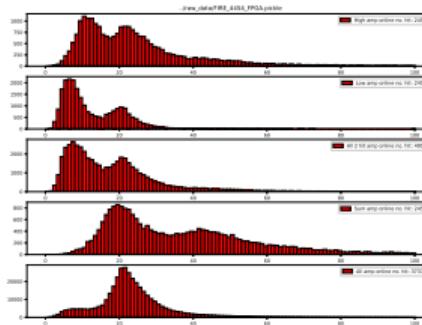

(a) Calice 74

(b) Calice 75

(c) Yan 1

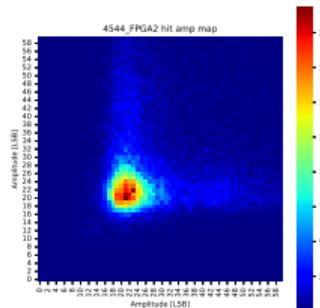

(d) Anton 1

Separation of 2 hits events types

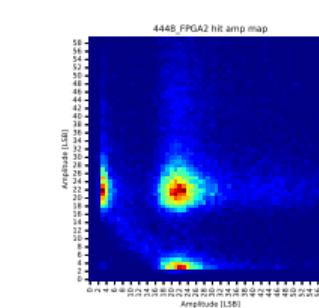

In Anton 1 and Yan
1 sensors there are
clearly visible
differences in sum of
amplitudes in event.
Does big fraction of
one particle 2-hit
events come from:

- ▶ charge sharing?
 - ▶ cross-talk?

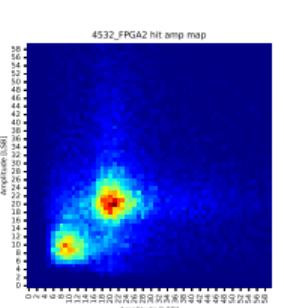

How can we explain this distribution?

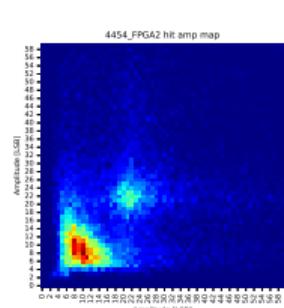

(a) Calice 74

(d) Anton 1

Amplitude of 2 hits events

By making this separation, we are trying to observe 1-particle events and 2-particle events in 2-hit events.

amplitude sum above 35

Conclusions

- ▶ 2-hit 2-particle events (why this occur so often $3 \pm 1\%$?)
- ▶ In GaAs sensors there is clearly visible anisotropy in 2-hit 1-particle events along y-axis same direction as trace in sensor. Cross-talk?
- ▶ In GaAs sensors in 2-hit 1-particle events amplitude is equally shared between hits. Charge sharing?
