Automation & Optimization at GSI with Geoff

EUROLABS (CEN) ESSI FAR

GSI/FAIR Overview

Automation & Optimization with Python

- beam steering and focusing (TK, X2)
- multi-turn injection loss minimization (SIS18)
- closed-orbit correction for non-standard optics (SIS18)
- beam-based magnetic field errors identification (SIS18)
- slow extraction loss minimization (SIS18)
- beam steering and focusing (FRS)

Methods of Interest

- numerical + Bayesian optimization (BO)
- physics-informed + multi-fidelity BO
- multi-objective optimization with BO
- mixed-method BO + extremum seeking
- data-driven model predictive control (MPC)
- reinforcement learning (RL)

Work power

- one scientific staff financed by EURO-LABS for three years
- one master student from PLUS (Salzburg)

< ロ > < 同 > < 三 > < 三 > < 三 > <

 several master/PhD students from TUDa (Darmstadt)

 \exists

Python Bridge

Key ingredient: Python bridge to GSI Control System

Python bridge to control system

- FESA: retrieve data from beam diagnostic devices
- LSA: log, calculate & verify settings for beam control

Geoff

https://gitlab.cern.ch/geoff/

- collaboration between CERN and GSI
- Python-based framework to harmonize libraries for optimization, optimal control and RL
- standardized interfaces and adapters for third-party packages
- optimization problems are packaged classes: allows optimization of very complex problems
- supports live plotting, data logging, and is agnostic of the controls system
- flexible, extensible, maintainable

Preprint: arxiv:2506.03796 Paper submitted to *SoftwareX*

SIS18 Multi-Turn Injection

- Liouville's theorem: beam can only go into free phase space
- Competing goals:
 - maximize gain factor factor (reach space charge limit)
 - minimize losses at septum (cause vacuum degradation)
- MTI model implemented in Xsuite for fast tracking

- beam position + tune most important
- all parameters have higher order dynamics (shown by σ/μ*)

- E

Э

Automation & Optimization at GSI with Geoff

Numerical Optimization

- example: BOBYQA
- deterministic, derivative-free black-box optimizer
- sequential trust-region algorithm with quadratic approximations to the objective function
- + easy to use, more time for problem formulation, system interaction, data analysis
- + few hyperparameters to tune
- + low computational cost
- + resistant to noise and measurement errors
- starts from scratch each time
- less reliable with non-convex problems

1 C. Cartis, arXiv:1804.00154 (2018), https://pypi.org/project/Py-BOBYQA

GP-MPC at SIS18

(S. Appel, B. Halilovic)

- combines Gaussian Processes with Model Predictive Control
- GP trained on real measurements or simulations
- controller predicts next action based on GP model
- data-effcient, noise-robust

GP-MPC at SIS18

Training results on simulation based on XSuite:

(S. Appel, B. Halilovic) 《 다 > 《 큔 > 《 흔 > 《 흔 > 흔 - 키 익 은 ·

Multi-Objective Bayesian Optimization

- competing goals: maximize number of injections, minimize loss
- Pareto front: set of solutions strictly better than others
- prior art: simulation with genetic algorithms (S. Appel)

Possible upgrade for SIS18 injection

 SIS18 uses wide range of ions (from protons to uranium)

- \Rightarrow injection via charge exchange is impractical
- possible upgrade: two-plane injection
 - tilt injection septum
 - \Rightarrow use vertical phase space
 - ⇒ overlap beamlets without violating Liouville's theorem

Drawbacks:

- requires replacement of injection line and area
- doubles number of injection parameters

10/16

(S.Appel)

Exploration of Novel Optimizers at the X2 Beamline

- goal: combine gradient-free global + gradient-based local optimization
- BO2ES: two phases of optimization
 - 1. Bayesian Optimization (efficient global exploration)
 - 2. Extremum Seeking (finetuning of best candidate)

Fragment Separator (FRS) and Super-FRS

1500

13 ±13 mrad

±40 ±20 mrad

- investigates nuclear structure of exotic nuclei
- produces, separates and identifies exotic nuclei
- sends them to downstream experiments or storage ring
- Super-FRS: higher acceptance, more complex (4× more magnets), gain factors between 1000 (12 C) and 7500 (132 Sn)

FRS

Super-FRS

18 Tm

20 Tm 2.5 %

FRS and Super-FRS: Goals

Motivation

- scale: manual setup too time consuming
- complexity: different optical modes per user
- = accuracy: scaling for same optics but different $B\rho$ not accurate enough

Observables

- profile grid histograms
- phase space spectra from tracking detectors

Machine Interface

- LSA database (trim steerers, magnets)
- FESA (SIS18 monitoring)
- Go4 (experiment-side TPC, current grids)

Optimization Goals

0th order: center the beam (vertical steerers, main dipoles) 1st order: set focus, dispersion (quadrupoles) 2nd order: minimize aberrations (sextupoles) 3rd order: minimize aberrations (octupoles, S-FRS only)

Figure: Track classification (simulation with disabled sextupoles)

(D. Kallendorf, master's thesis)

FRS and Super-FRS: Observables

Central spot:

- Twiss parameters
- Non-dispersive 1st-order transfer matrix

Outer spots:

- 1st-/2nd-order dispersive transfer matrix elements
- **Goal:** Bring the spectra as close as possible to desired 1st order parameters
 - ⇒ optimize direct observables, not individual matrix elements!

→ ∃ →

Э

FRS and Super-FRS: Results

Proof of principle:

- 1. **steer beams** at target
- 2. tune quadrupoles to focus beam (central spot upright)
- 3. tune sextupoles to remove focal-plane tilt and "banana" deformation

Illustration of FRS Dispersive Area

EURO-LABS

IS SI FAR

Next step

- use other observables
- tune entire 1st-order optics
- include dispersion

Summary

- Python framework to facilitate transition from numerical optimization to RL
- only requirement: Python interface to the controls system
- widespread use at CERN, proof of concept at GSI

Outlook

- ecosystem keeps shifting: Gymnasium ightarrow 1.0, NumPy ightarrow 2.0
- further development of the GUI app
- more experiments at GSI and CEA Paris-Saclay
