- from 2001 to 2004 ultra high energy cosmic rays (UHECR)
- from 2015 to 2016 axion physics

It was really a great pleasure to work with Andreas! Thank you!

We wanted to intensify/institutionalize  $\Rightarrow$  excellence initiative

I will choose one work from each time period

- Z-burst explanation of UHECRs and neutrino masses
- topological susceptibility at large temperatures

# The most entertaining research time: Z-burst physics

# The most entertaining research time: Z-burst physics

ultra-high-energy cosmic ray (UHECR):  
energy greater than 1 EeV ( $10^{18}$  eV)

## The most entertaining research time: Z-burst physics

ultra-high-energy cosmic ray (UHECR):  
energy greater than 1 EeV ( $10^{18}$  eV)

University of Utah's Fly's Eye 1991:  
 $3.2 \cdot 10^{21}$  eV nucleus as a 100 km/h baseball

# The most entertaining research time: Z-burst physics

ultra-high-energy cosmic ray (UHECR):  
energy greater than 1 EeV ( $10^{18}$  eV)

University of Utah's Fly's Eye 1991:  
 $3.2 \cdot 10^{21}$  eV nucleus as a 100 km/h baseball

GZK cutoff-paradox: why do we observe them?  
within 50 Mpc they should interact with CMB  
One should see a cutoff somewhere below  $10^{20}$  eV

# The most entertaining research time: Z-burst physics

ultra-high-energy cosmic ray (UHECR):  
energy greater than 1 EeV ( $10^{18}$  eV)

University of Utah's Fly's Eye 1991:  
 $3.2 \cdot 10^{21}$  eV nucleus as a 100 km/h baseball

GZK cutoff-paradox: why do we observe them?  
within 50 Mpc they should interact with CMB  
One should see a cutoff somewhere below  $10^{20}$  eV

UHECR neutrinos hitting relic neutrinos  
Z-burst  $\Rightarrow$  UHECR hadrons  
scenario depends on the neutrino mass

# The Z-burst setup

# The Z-burst setup

Relic neutrinos: decoupled at  $T=1$  MeV and  $t=1$  second

# The Z-burst setup

Relic neutrinos: decoupled at  $T=1$  MeV and  $t=1$  second

Their predicted number density:  $56/\text{cm}^3$  (comparable to CMB)

# The Z-burst setup

Relic neutrinos: decoupled at  $T=1$  MeV and  $t=1$  second

Their predicted number density:  $56/\text{cm}^3$  (comparable to CMB)

Z resonance production:  $\nu\bar{\nu} \longrightarrow Z \longrightarrow \text{hadrons}$

# The Z-burst setup

Relic neutrinos: decoupled at  $T=1$  MeV and  $t=1$  second

Their predicted number density:  $56/\text{cm}^3$  (comparable to CMB)

Z resonance production:  $\nu\bar{\nu} \longrightarrow Z \longrightarrow \text{hadrons}$

$$E_{\nu}^{\text{res}} = M_Z^2/2m_{\nu} = 4.2 \cdot 10^{21} \text{ eV} \cdot (1 \text{ eV}/m_{\nu})$$

# The Z-burst setup

Relic neutrinos: decoupled at  $T=1$  MeV and  $t=1$  second

Their predicted number density:  $56/\text{cm}^3$  (comparable to CMB)

Z resonance production:  $\nu\bar{\nu} \longrightarrow Z \longrightarrow \text{hadrons}$

$$E_{\nu}^{\text{res}} = M_Z^2/2m_{\nu} = 4.2 \cdot 10^{21} \text{ eV} \cdot (1 \text{ eV}/m_{\nu})$$

decreasing  $\nu$  flux  $\Rightarrow$  largest  $m_{\nu}$  needs the smallest E: dominant

# The Z-burst setup

Relic neutrinos: decoupled at  $T=1$  MeV and  $t=1$  second

Their predicted number density:  $56/\text{cm}^3$  (comparable to CMB)

Z resonance production:  $\nu\bar{\nu} \longrightarrow Z \longrightarrow \text{hadrons}$

$$E_{\nu}^{\text{res}} = M_Z^2/2m_{\nu} = 4.2 \cdot 10^{21} \text{ eV} \cdot (1 \text{ eV}/m_{\nu})$$

decreasing  $\nu$  flux  $\Rightarrow$  largest  $m_{\nu}$  needs the smallest E: dominant

We can fit  $m_{\nu}$ , absolute scale, to the observed UHECR spectrum

Result:  $0.08 \text{ eV} < m_{\nu} < 0.40 \text{ eV}$ , similar scale as the mass differences

# The Z-burst setup

Relic neutrinos: decoupled at  $T=1$  MeV and  $t=1$  second

Their predicted number density:  $56/\text{cm}^3$  (comparable to CMB)

Z resonance production:  $\nu\bar{\nu} \longrightarrow Z \longrightarrow \text{hadrons}$

$$E_{\nu}^{\text{res}} = M_Z^2/2m_{\nu} = 4.2 \cdot 10^{21} \text{ eV} \cdot (1 \text{ eV}/m_{\nu})$$

decreasing  $\nu$  flux  $\Rightarrow$  largest  $m_{\nu}$  needs the smallest E: dominant

We can fit  $m_{\nu}$ , absolute scale, to the observed UHECR spectrum

Result:  $0.08 \text{ eV} < m_{\nu} < 0.40 \text{ eV}$ , similar scale as the mass differences

After over two decades, we still don't know the absolute scale

# The most entertaining research time: Z-burst physics

At least three great successes

- (a) explain UHECR & the GZK cutoff-paradox
- (b) give an absolute value for  $m_\nu$
- (c) prove the existence of relic neutrinos

# The most entertaining research time: Z-burst physics

At least three great successes

- (a) explain UHECR & the GZK cutoff-paradox
- (b) give an absolute value for  $m_\nu$
- (c) prove the existence of relic neutrinos

At least three great successes

- (a) explain UHECR & the GZK cutoff-paradox
- (b) give an absolute value for  $m_\nu$
- (c) prove the existence of relic neutrinos

2017: instead of the 30 UHECR events, what could have confirmed AGASA

Auger saw only two events  $\Rightarrow$  GZK cutoff is there

(Earlier large E/flux results: probably incorrect energy calibration issue)

## Fun part: density distribution on all four

differential proton flux is proportional  
to the density of relic neutrinos

## Fun part: density distribution on all four

differential proton flux is proportional  
to the density of relic neutrinos

it follows the total mass distribution  
however, with less clustering

## Fun part: density distribution on all four

differential proton flux is proportional  
to the density of relic neutrinos

it follows the total mass distribution  
however, with less clustering

vary the density between these two cases

## Fun part: density distribution on all four

differential proton flux is proportional  
to the density of relic neutrinos

it follows the total mass distribution  
however, with less clustering

vary the density between these two cases

total mass distribution within 100 Mp  
from peculiar velocity measurements

relative overdensities of 2-3

## Fun part: density distribution on all four

differential proton flux is proportional  
to the density of relic neutrinos

it follows the total mass distribution  
however, with less clustering

vary the density between these two cases

total mass distribution within 100 Mp  
from peculiar velocity measurements

relative overdensities of 2-3

printed small sections on A4 papers  
glued them to a large map  
read off the density using a ruler

## Literature: full QCD topological susceptibility

C.Bonati, M.d'Elia, G.Martinelli et al. JHEP 229 03, 155 (2016)

- brute force fully dynamic in the continuum up to  $\approx 4T_c$

## Literature: full QCD topological susceptibility

C.Bonati, M.d'Elia, G.Martinelli et al. JHEP 229 03, 155 (2016)

- brute force fully dynamic in the continuum up to  $\approx 4T_c$

Result:  $b \sim 3$  *unexpected* (DIGA etc.  $b \sim 8$ )

for  $T > 2$  GeV is larger than DIGA by **7-8 orders of magnitude**

## Literature: full QCD topological susceptibility

C.Bonati, M.d'Elia, G.Martinelli et al. JHEP 229 03, 155 (2016)

- brute force fully dynamic in the continuum up to  $\approx 4T_c$

Result:  $b \sim 3$  *unexpected* (DIGA etc.  $b \sim 8$ )

for  $T > 2$  GeV is larger than DIGA by **7-8 orders of magnitude**  
one order of magnitude shift for the axion dark matter window

## Literature: full QCD topological susceptibility

C.Bonati, M.d'Elia, G.Martinelli et al. JHEP 229 03, 155 (2016)

- brute force fully dynamic in the continuum up to  $\approx 4T_c$

Result:  $b \sim 3$  *unexpected* (DIGA etc.  $b \sim 8$ )

for  $T > 2$  GeV is larger than DIGA by **7-8 orders of magnitude**

one order of magnitude shift for the axion dark matter window

*crosses quenched* result at  $4T_c$  (for quenched  $\chi_t^{1/4}(4T_c) = 17$  MeV)

## Literature: full QCD topological susceptibility

for  $T > 2$  GeV is larger than DIGA by **7-8 orders of magnitude**

one order of magnitude shift for the axion dark matter window

*crosses quenched* result at  $4T_c$  (for quenched  $\chi_t^{1/4}(4T_c) = 17$  MeV)

⇒ further study is obviously necessary

## Fixed $Q$ integral - quenched/dynamical

Fixed  $Q$  simulation: extra acc/rej step at the end of each update, as lattice spacing decreased the acceptance gets better.

## Fixed Q integral - quenched/dynamical

Fixed Q simulation: extra acc/rej step at the end of each update, as lattice spacing decreased the acceptance gets better.

Test in quenched case: pure Wilson action upto  $7 \cdot T_c$  and  $8 \times 64^3$

## Fixed Q integral - quenched/dynamical

Fixed Q simulation: extra acc/rej step at the end of each update, as lattice spacing decreased the acceptance gets better.

Test in quenched case: pure Wilson action upto  $7 \cdot T_c$  and  $8 \times 64^3$

**standard method:** extrapolation using a fit;

**integral method;**

**Dilute Instanton Gas Approximation:**
