GROSSE HERAUSFORDERUNGEN

Action items from pre-approval talk:

- A_E and others: Compare if the templates for nuisances (`xsec_st`, FSR, PU) show real asymmetry
- Correct for factor 100 on results in slides/documentation
- Split JEC
- use theory NNLO/NLO ratio for top p_T reweighting
- check if you gain sensitivity by loosening the fiducial definition

What has changed since pre-approval

JEC 27 sources included - (FlavorQCD is also separated into Gluon,Bottom,Quark,Charm)

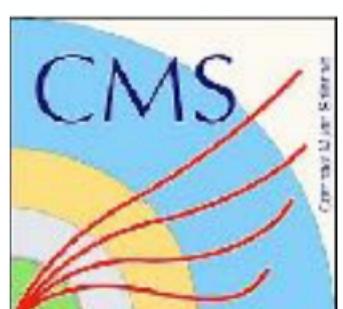

Taking into account the correlation across years as recommended
HLT uncorrelated across years

Top-pt-rew. changed from the data to theory based weights

Xsec unc. of ST and Wjets reduced from 30% to 15%

Relaxed definition of the fiducial-phase space (to mimic ATLAS)

- $\text{jet}_\text{pt} > 5\text{GeV}$
- No Gen M_{tt} cut

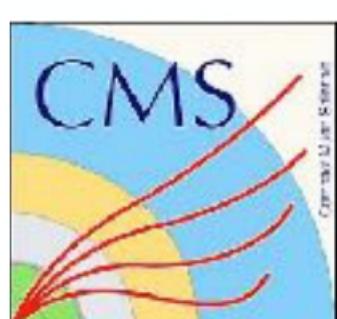

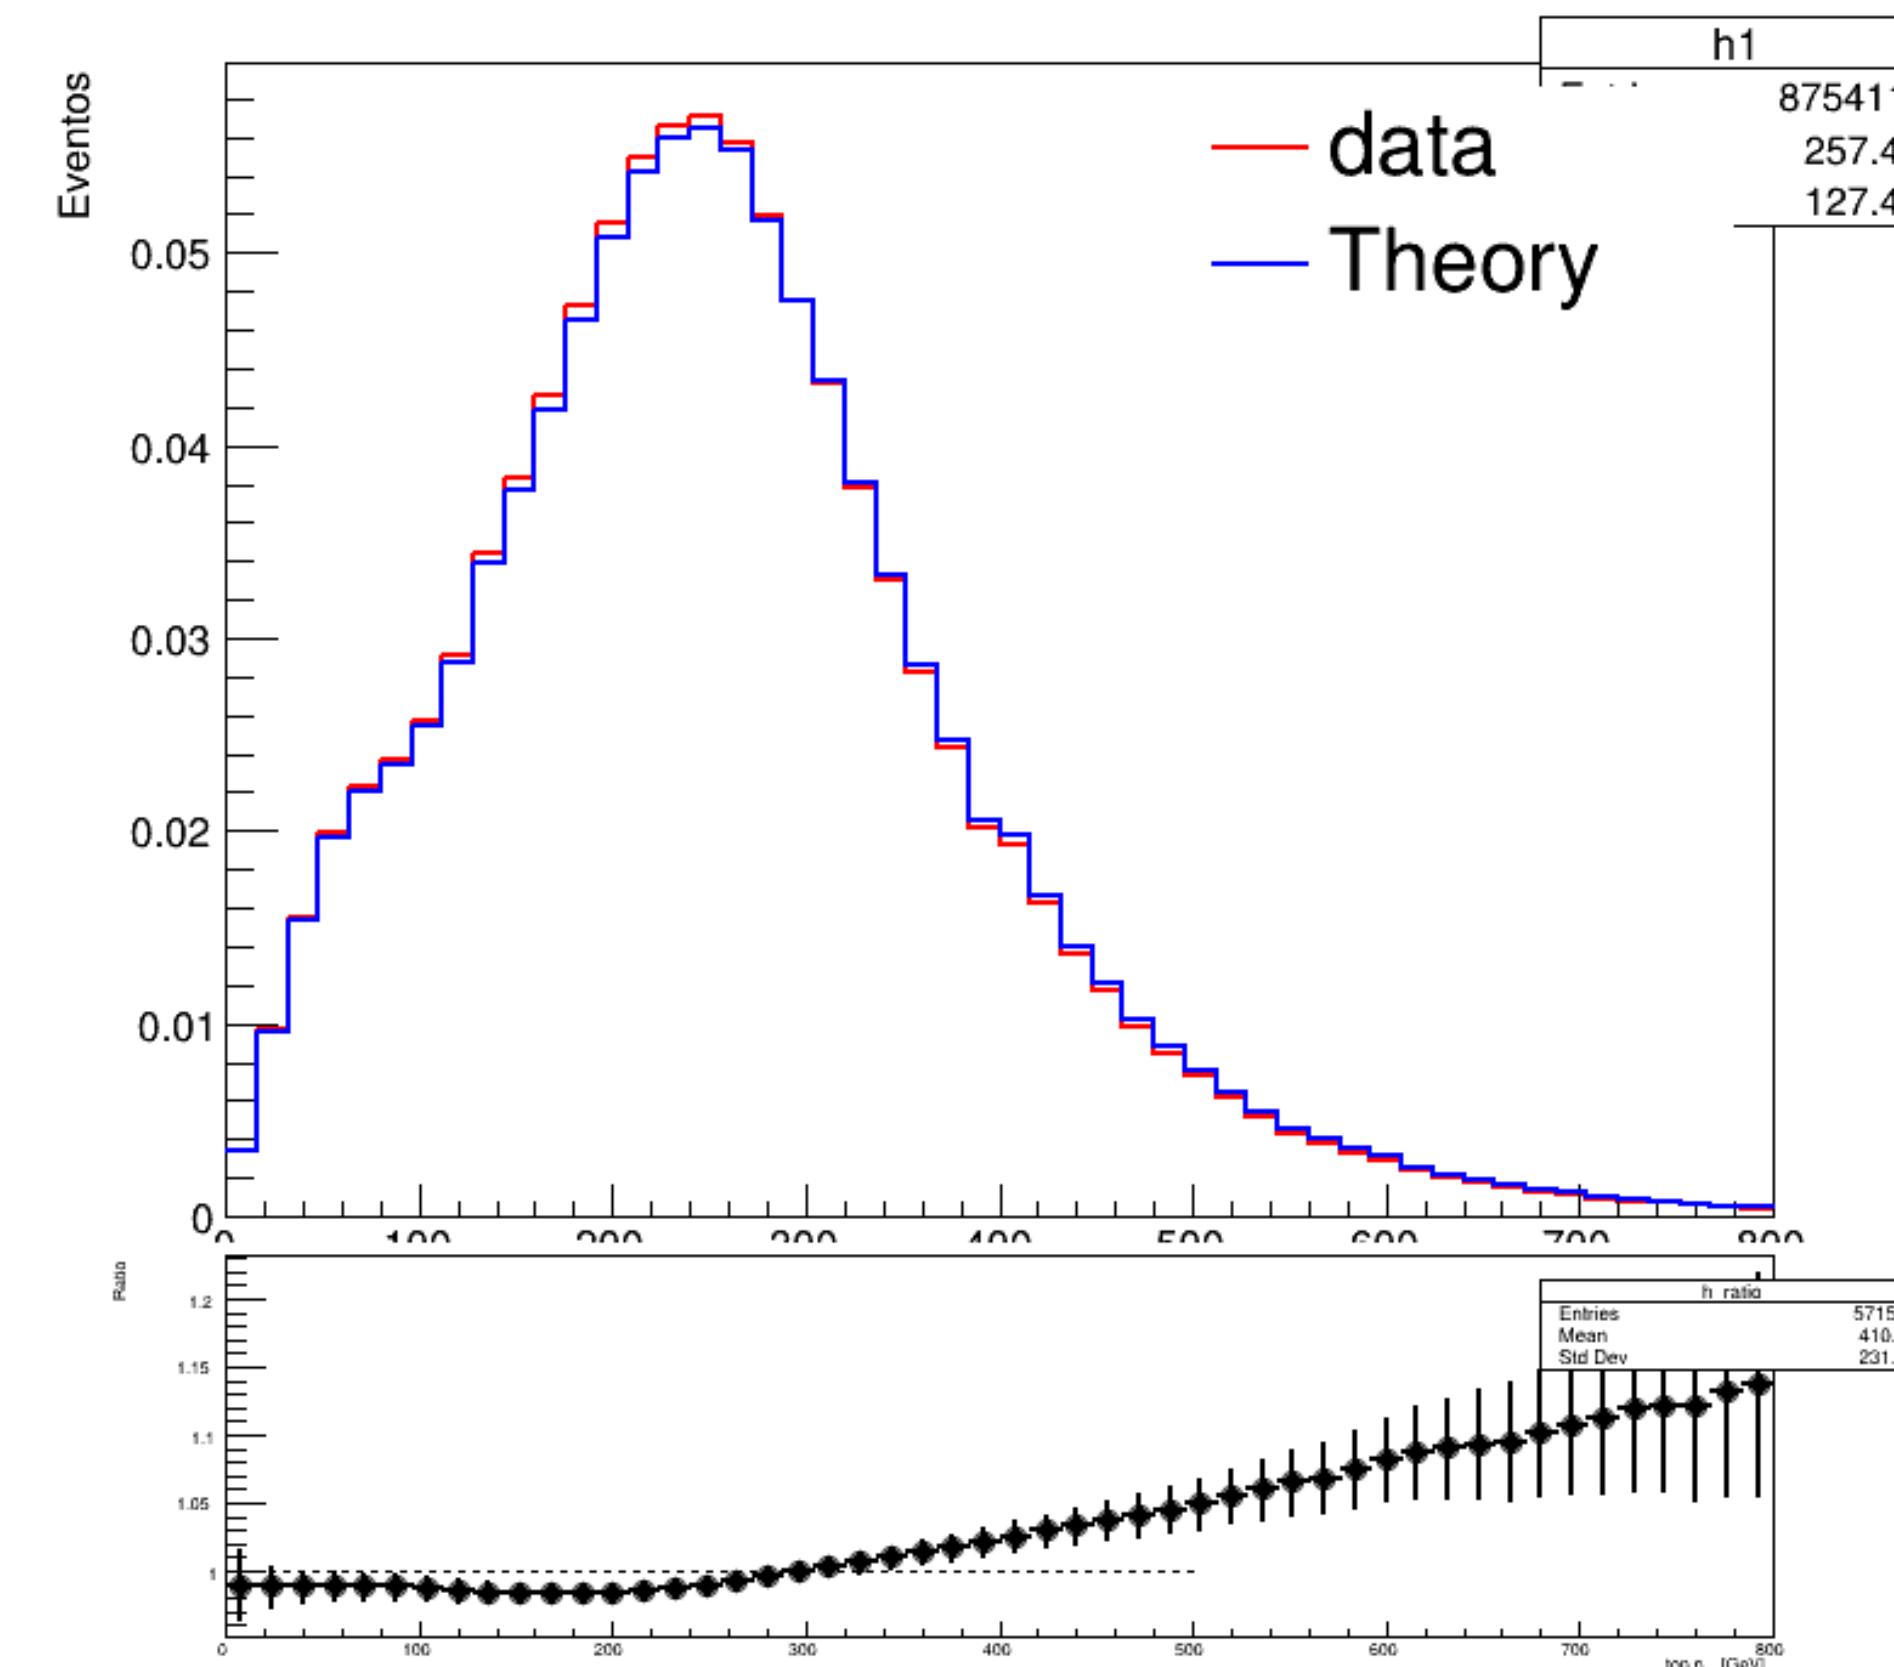

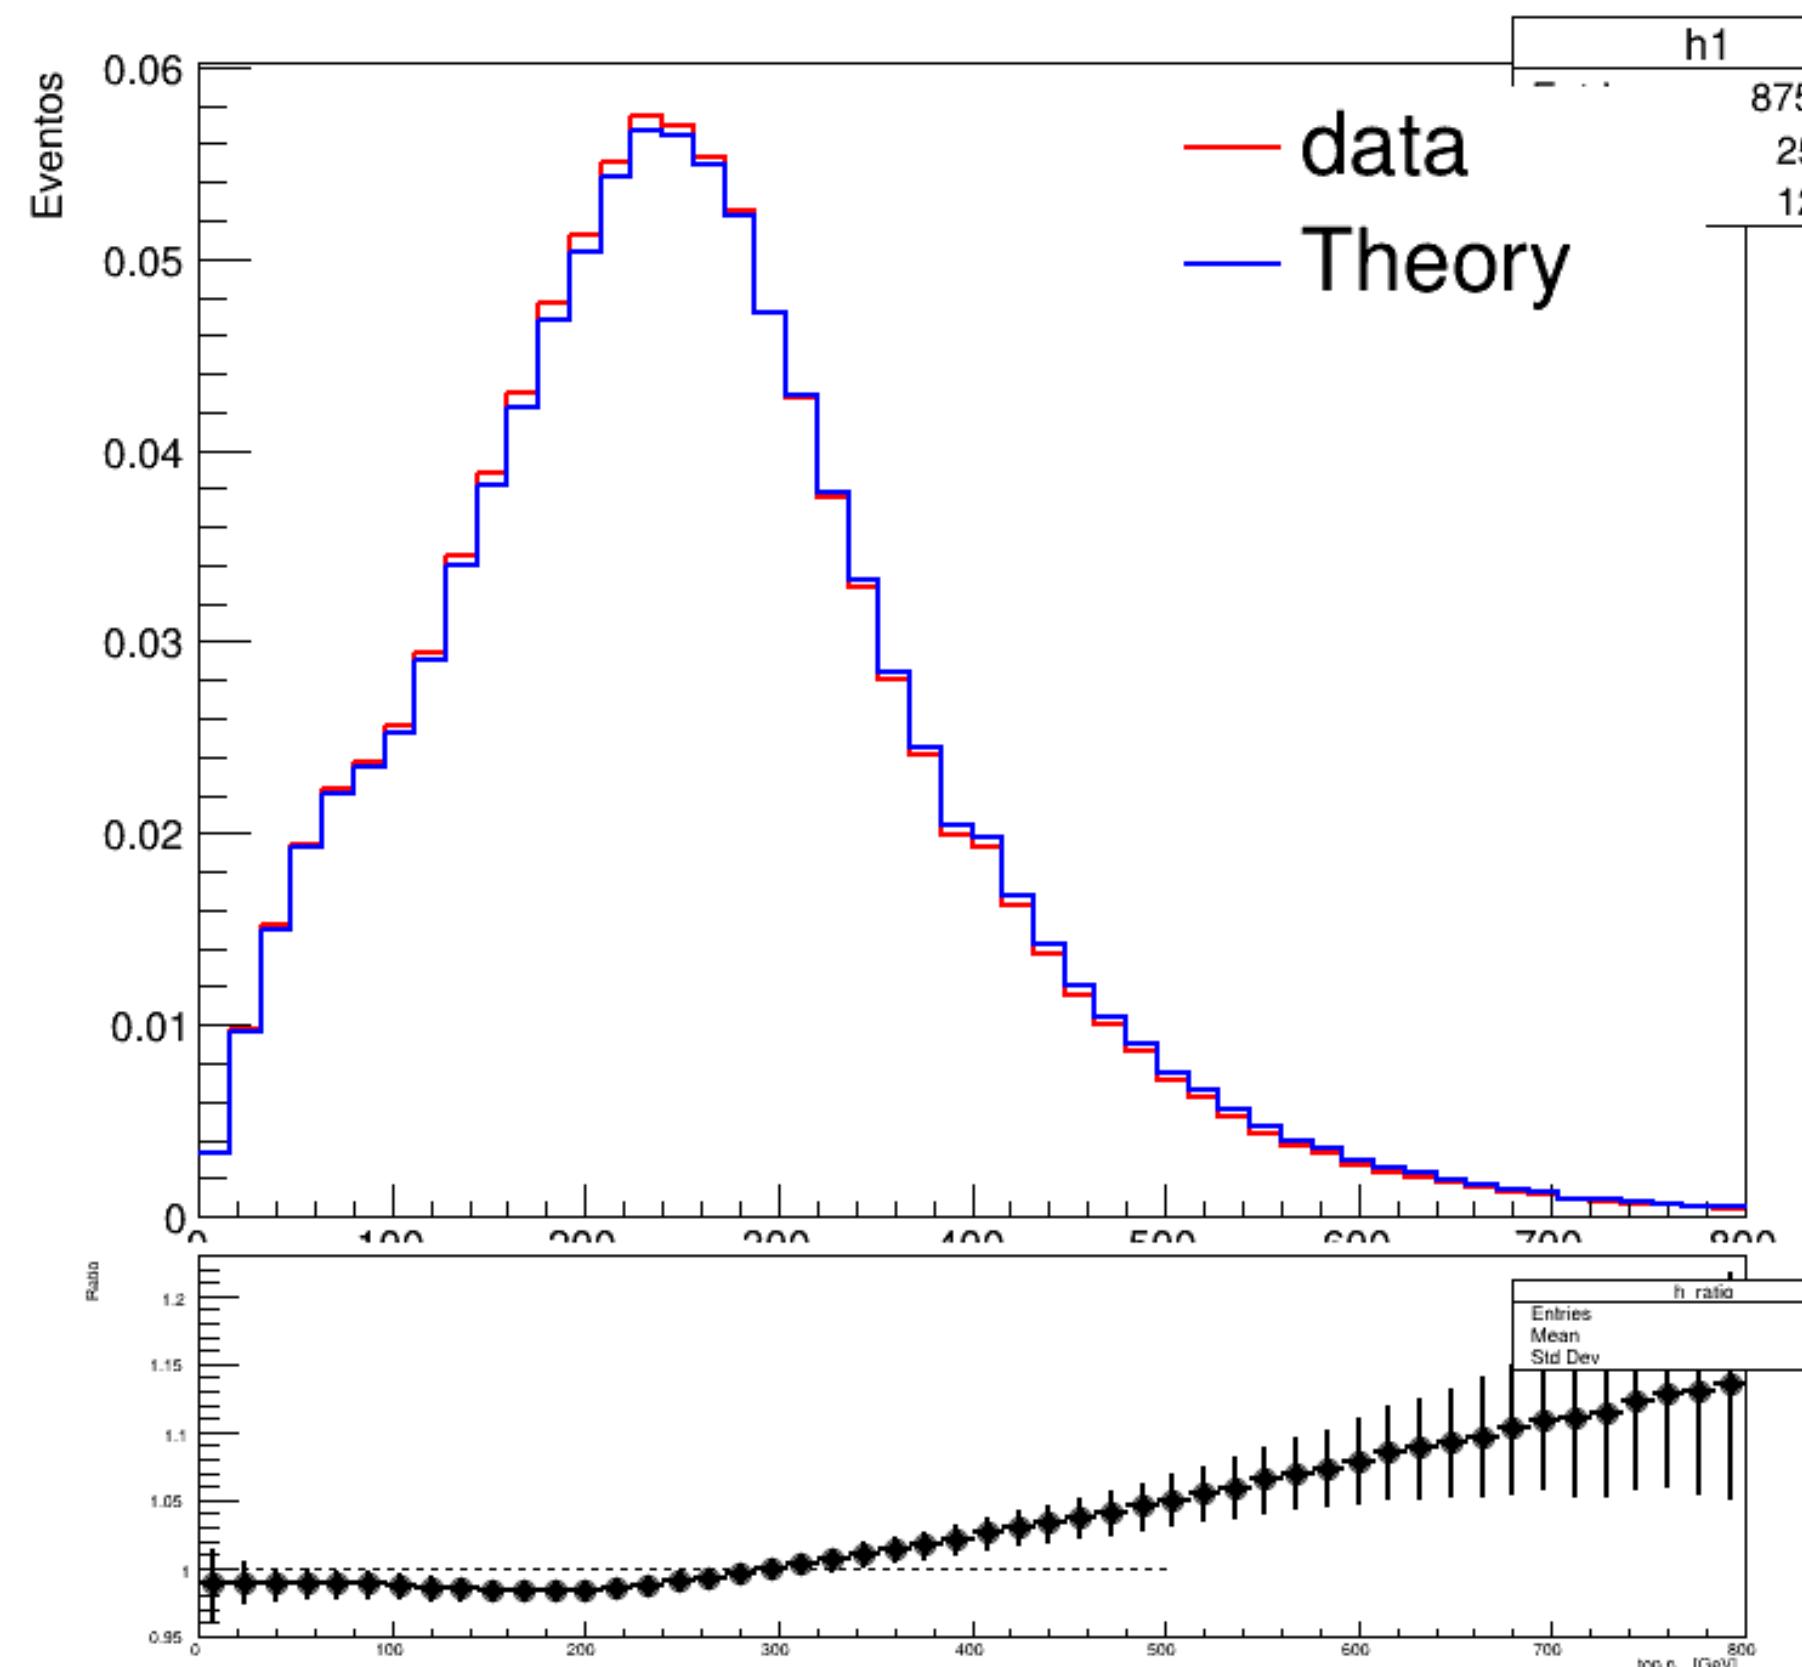

HELMHOLTZ

GROSSE HERAUSFORDERUNGEN

Comparison of old pt-rew vs new pt-rew

Change was done as requested, major change after $\text{pt} > 500 \text{ GeV}$.

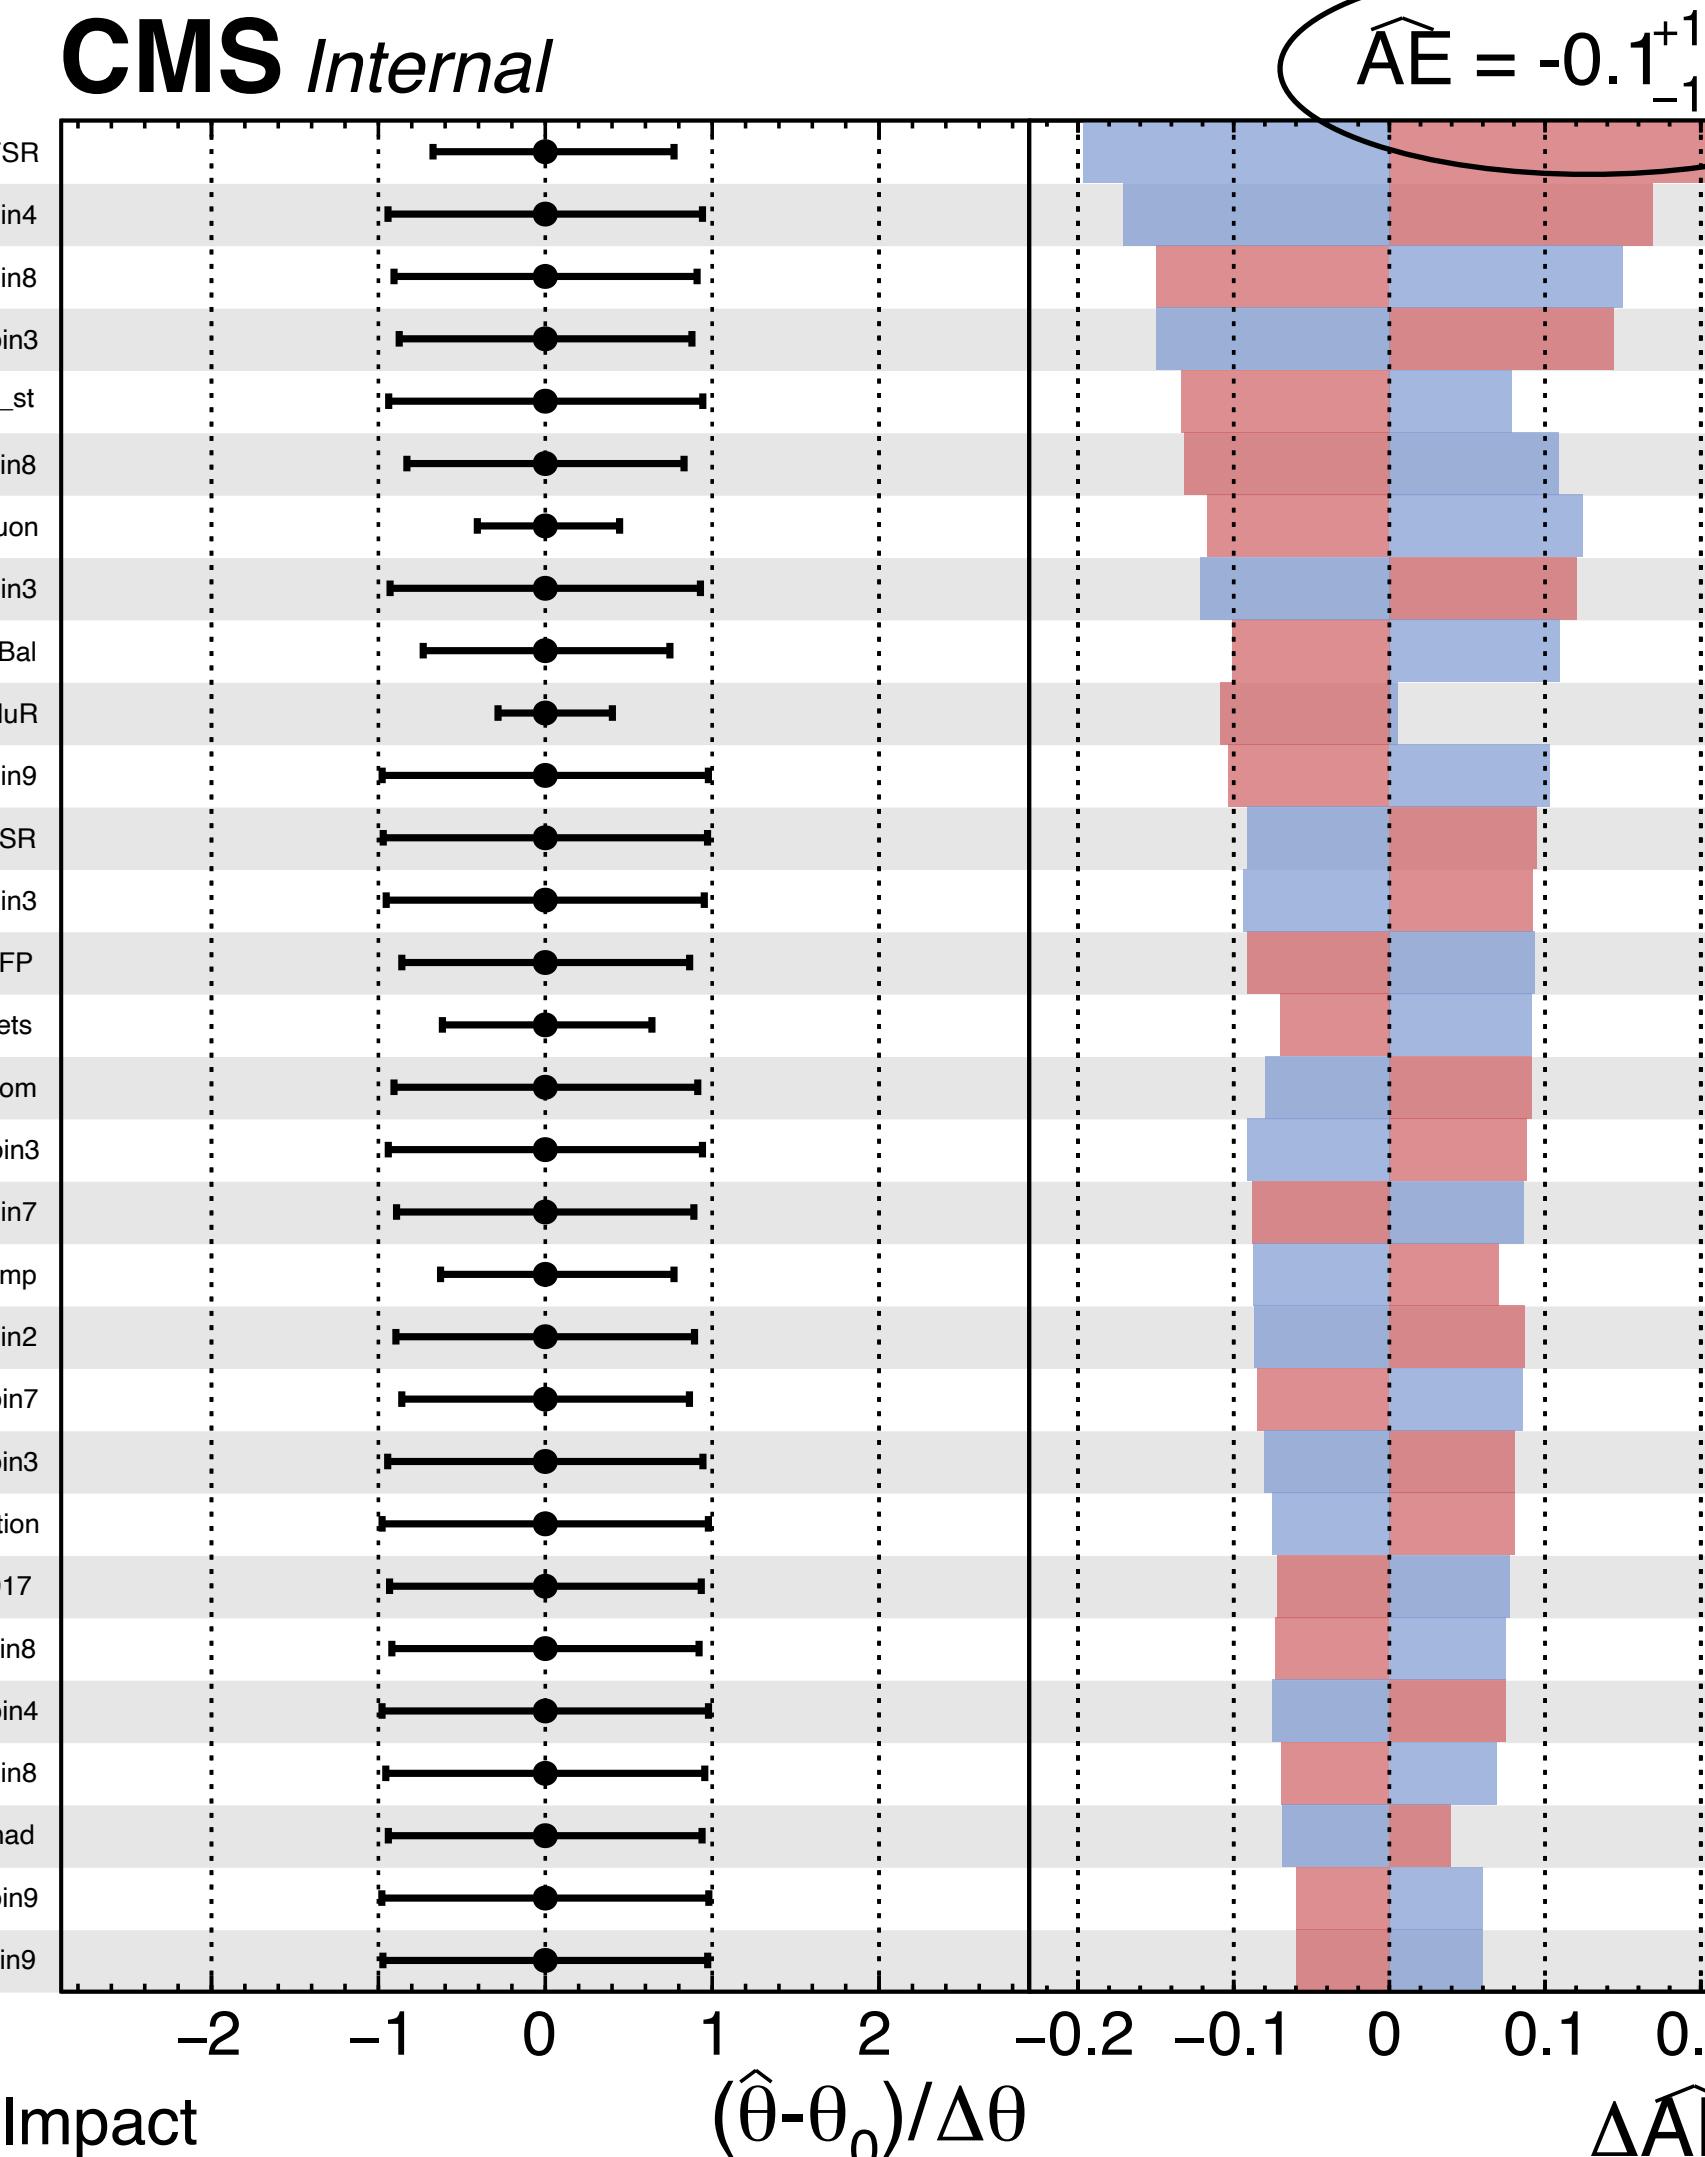

Peak $\sim 200 \text{ GeV}$. Data MC agreement still looks good. (See next slide)

New blinded results (A_E)

More competitive uncertainty

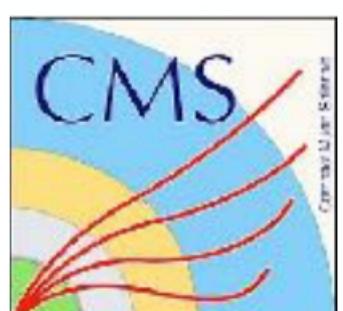

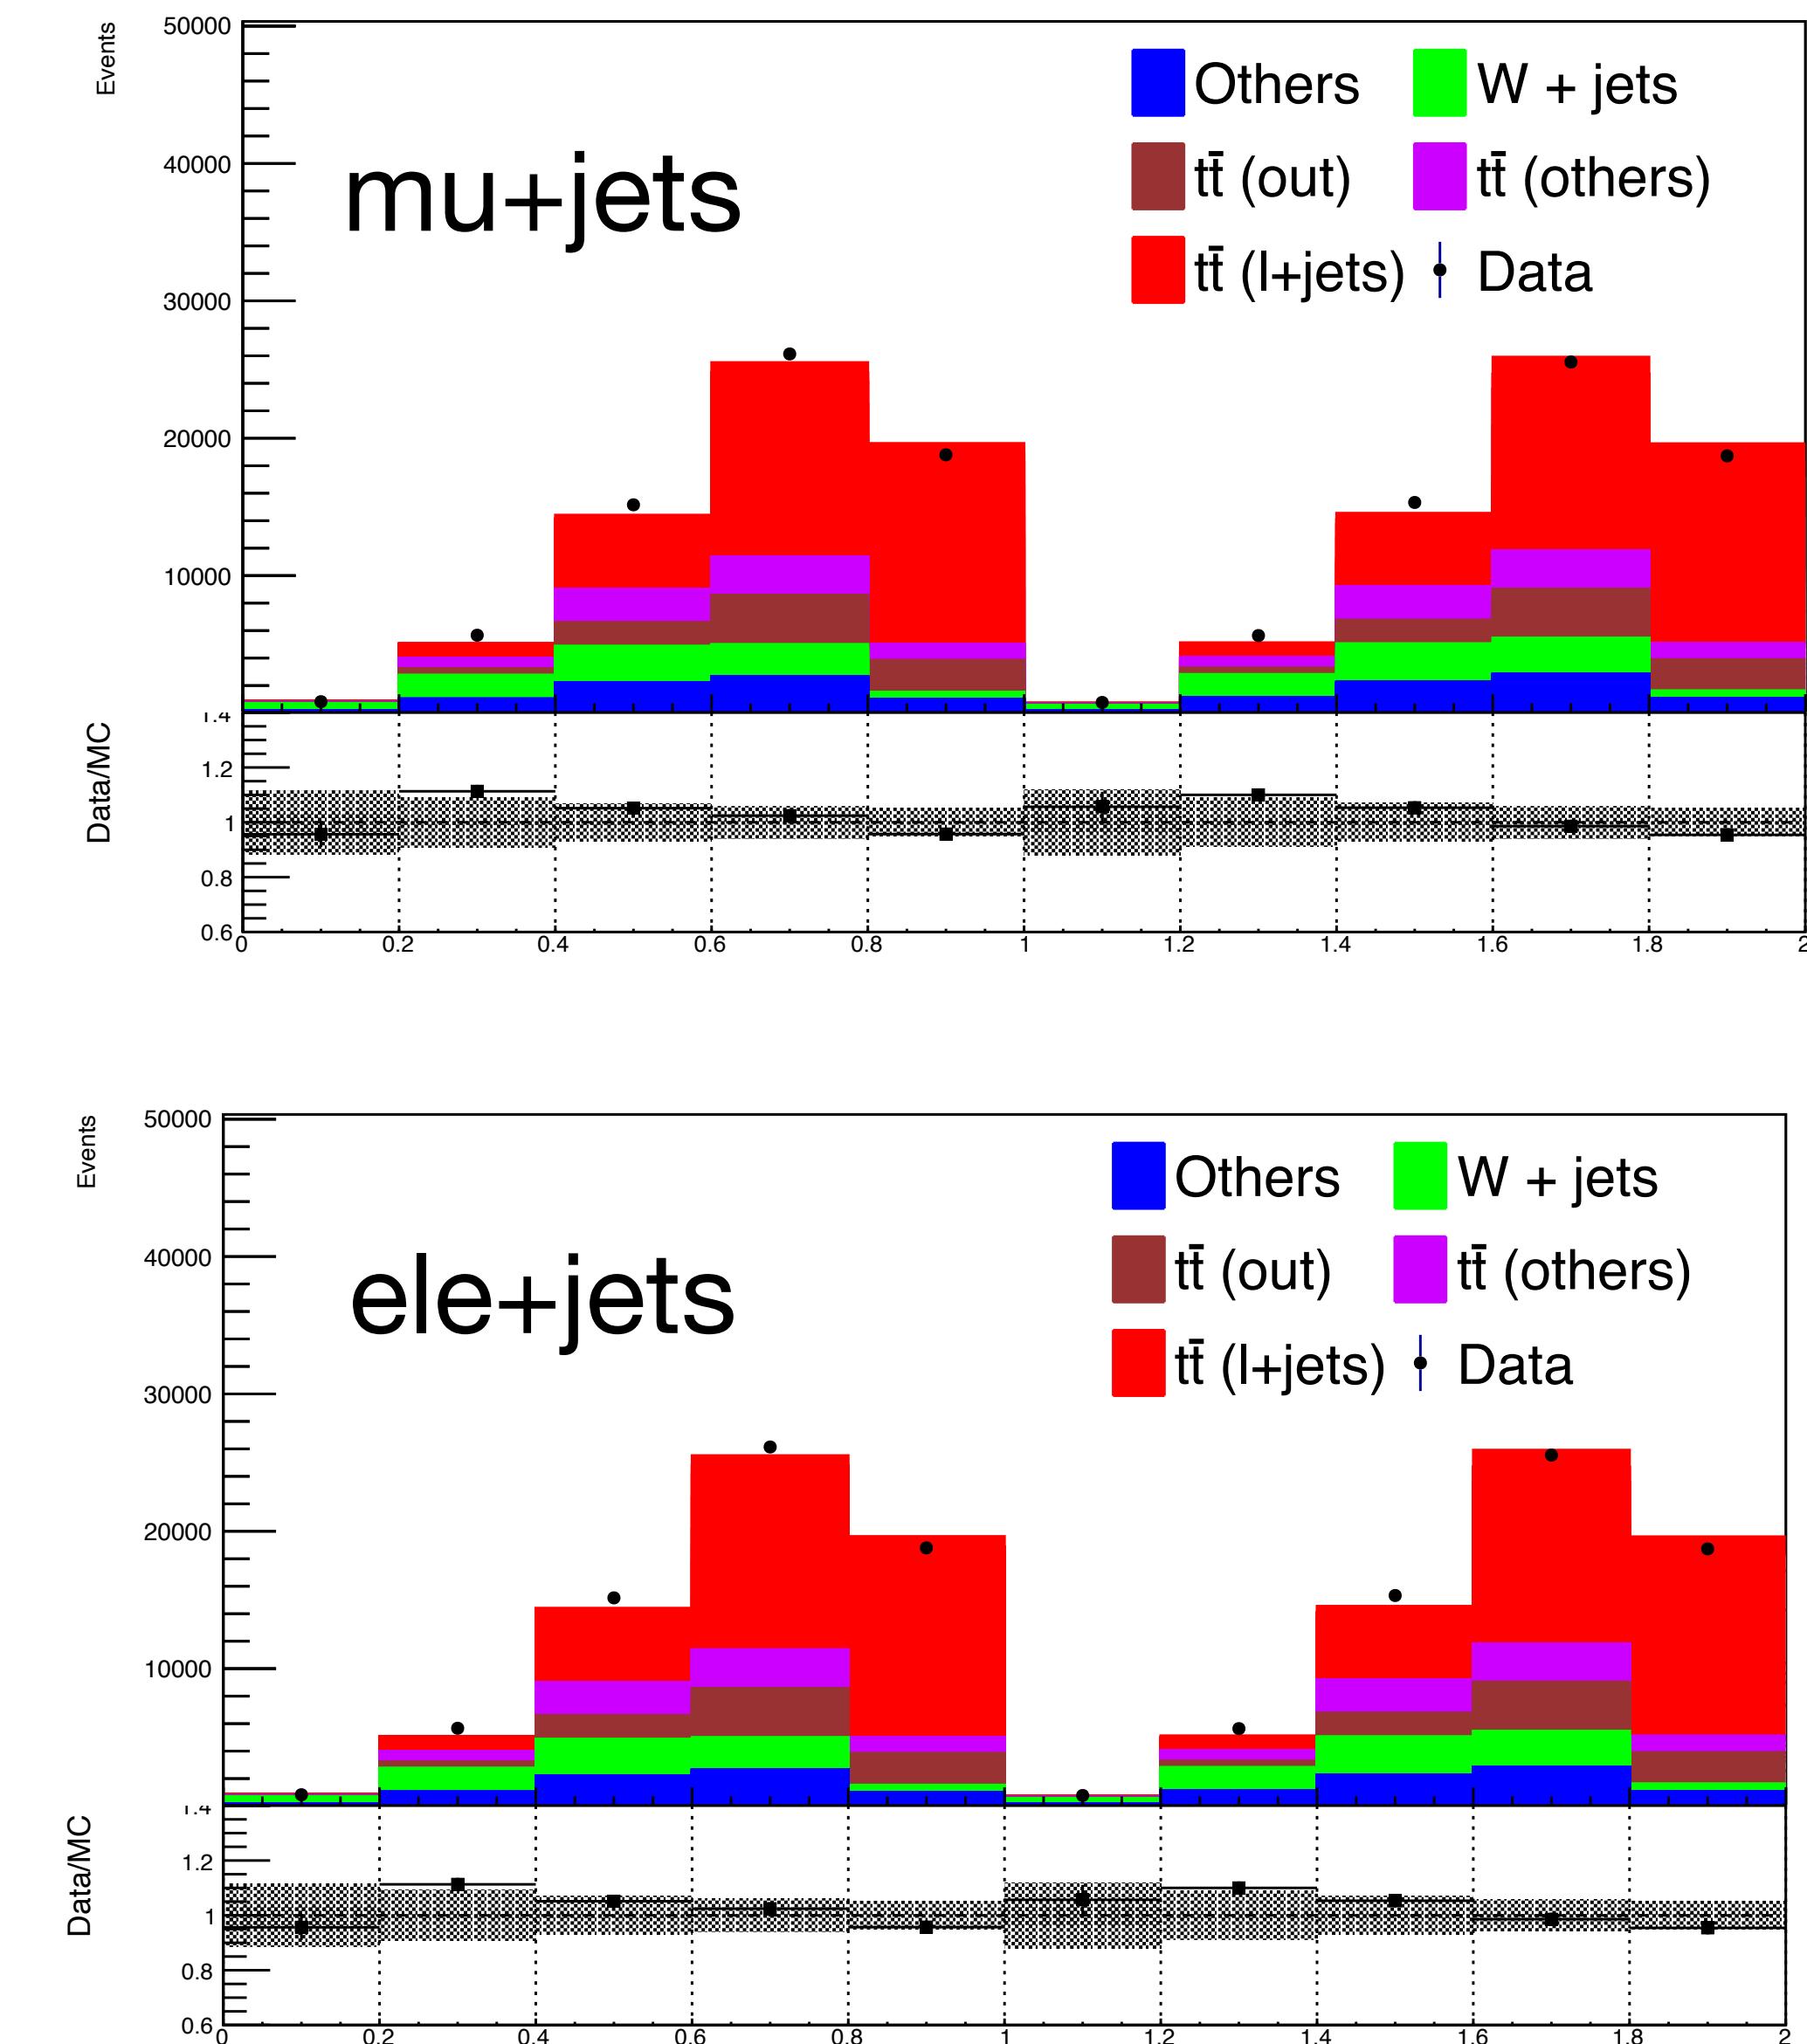

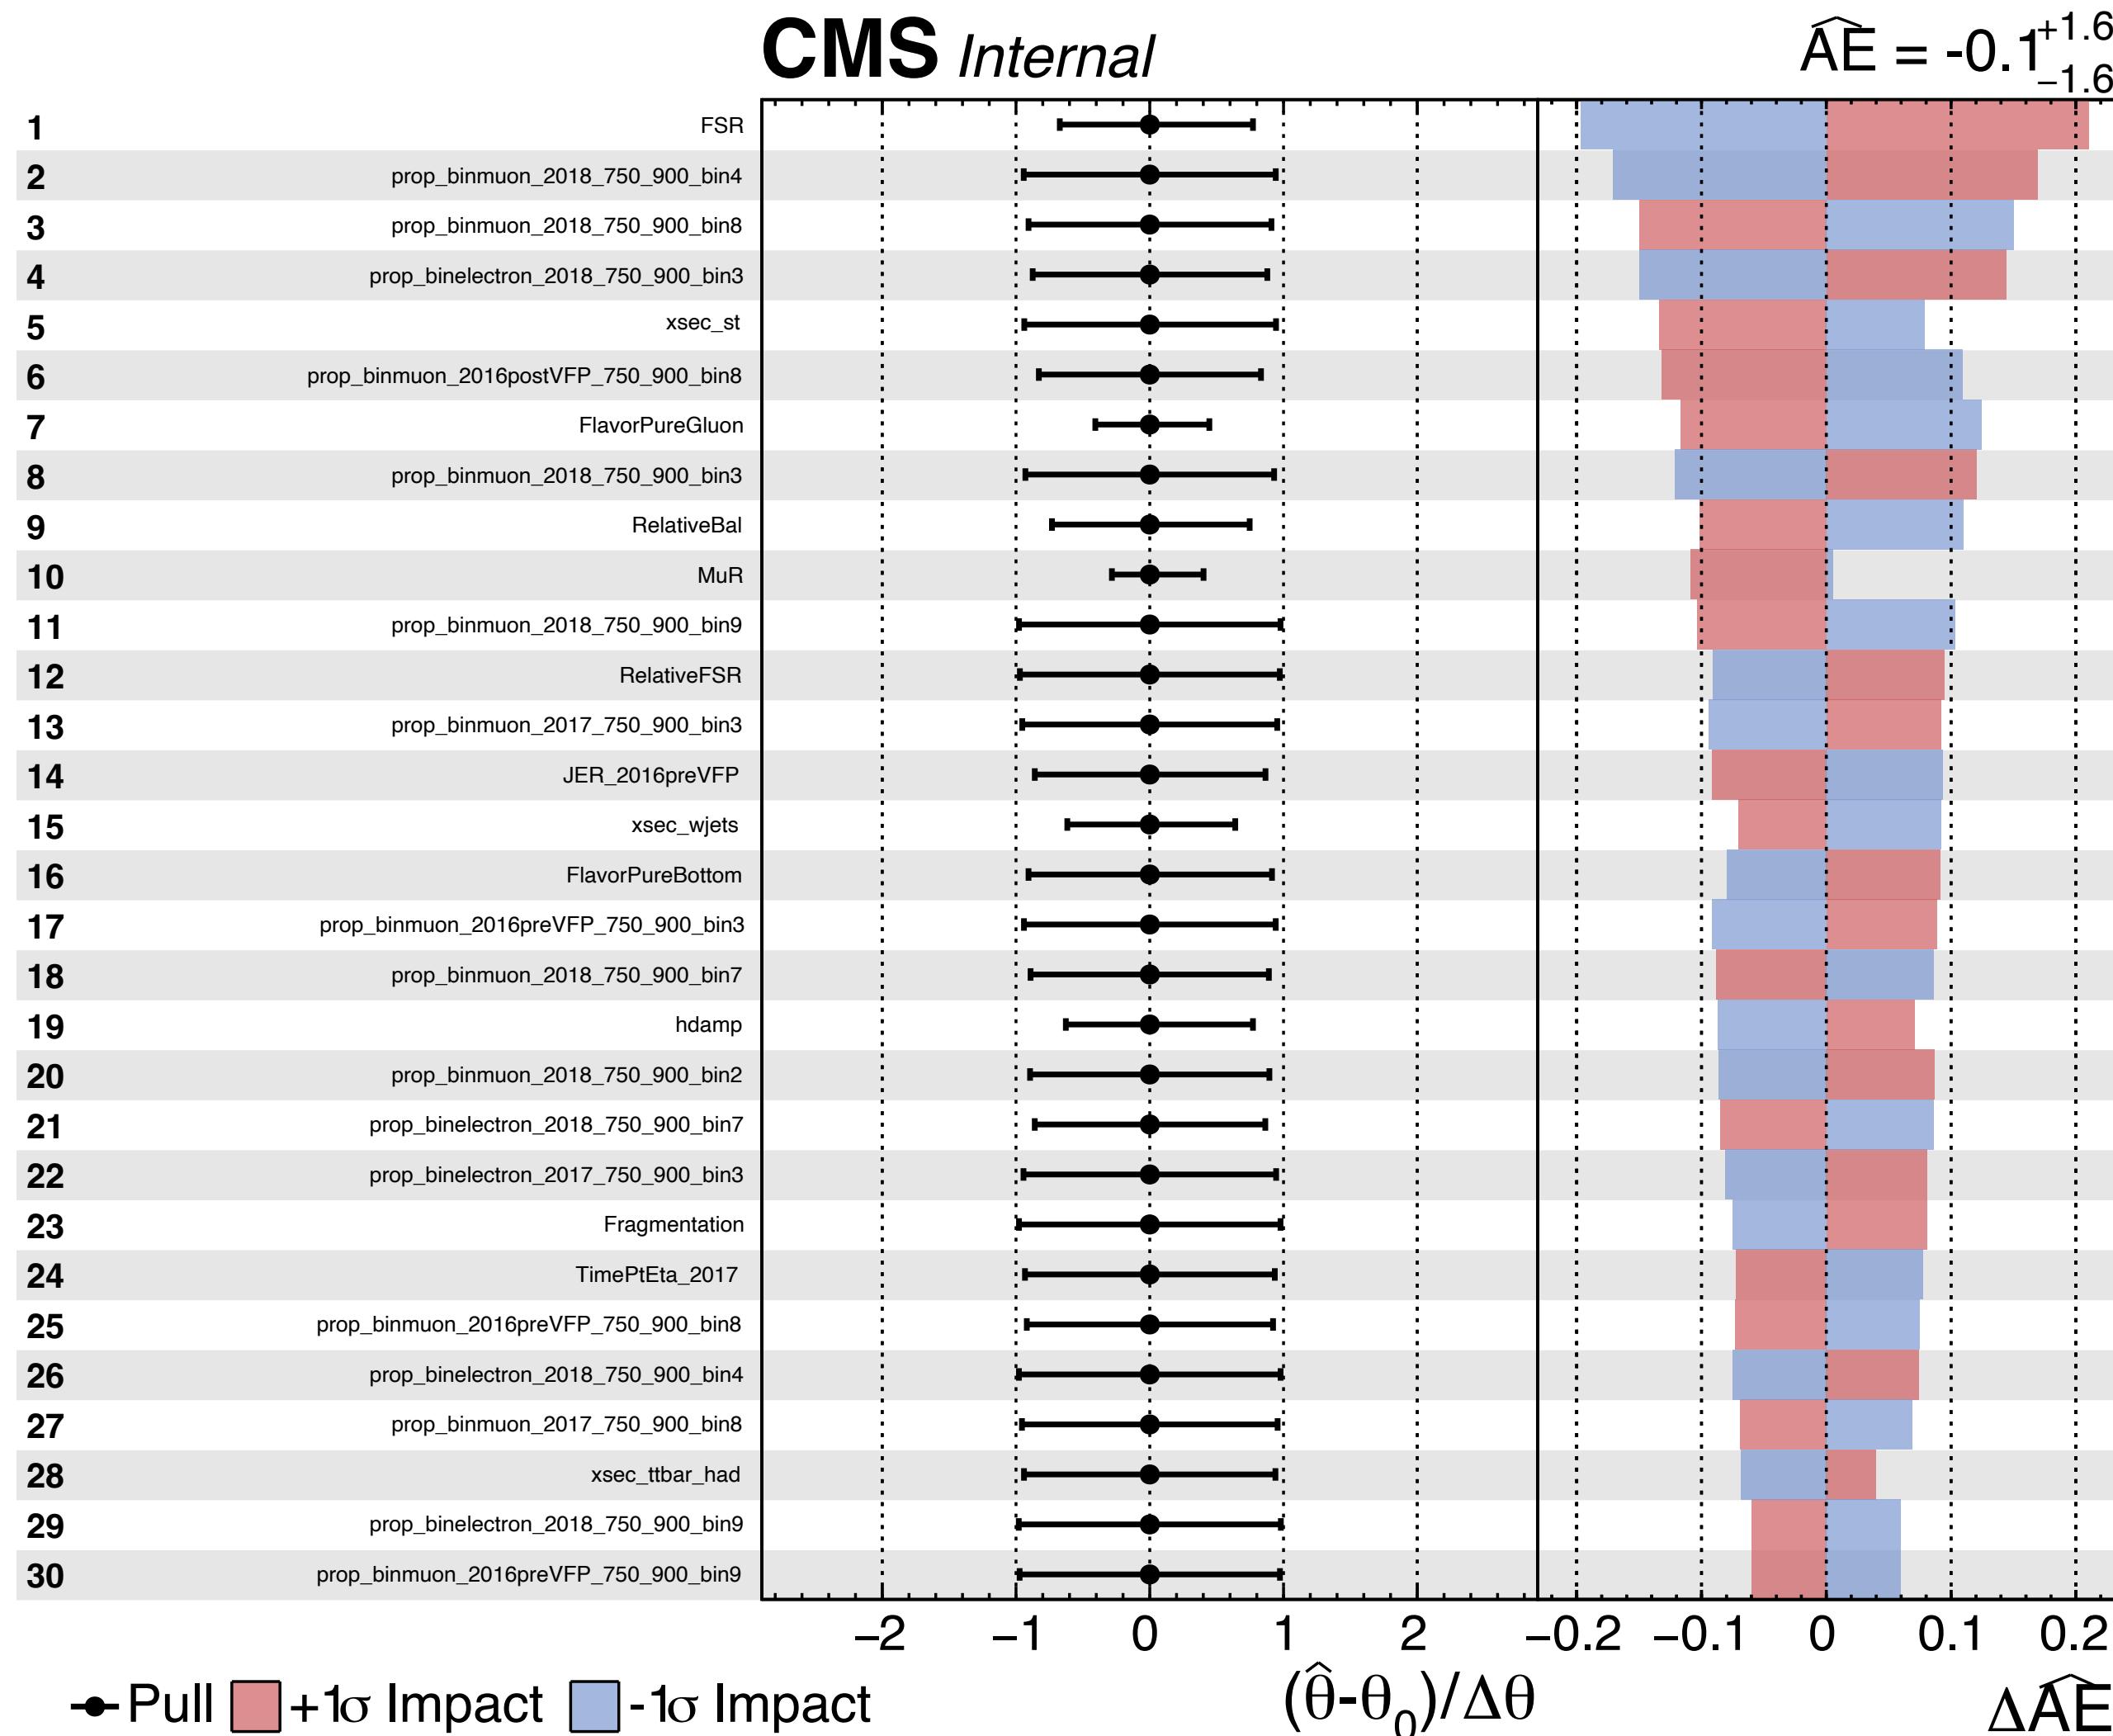

Mostly coming from
the new definition of
fiducial phase space.

More events enter in tt
“signal”

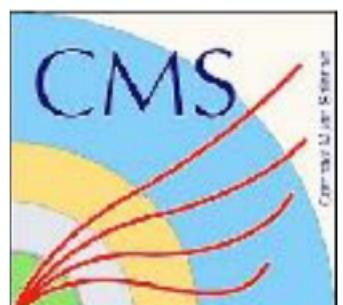

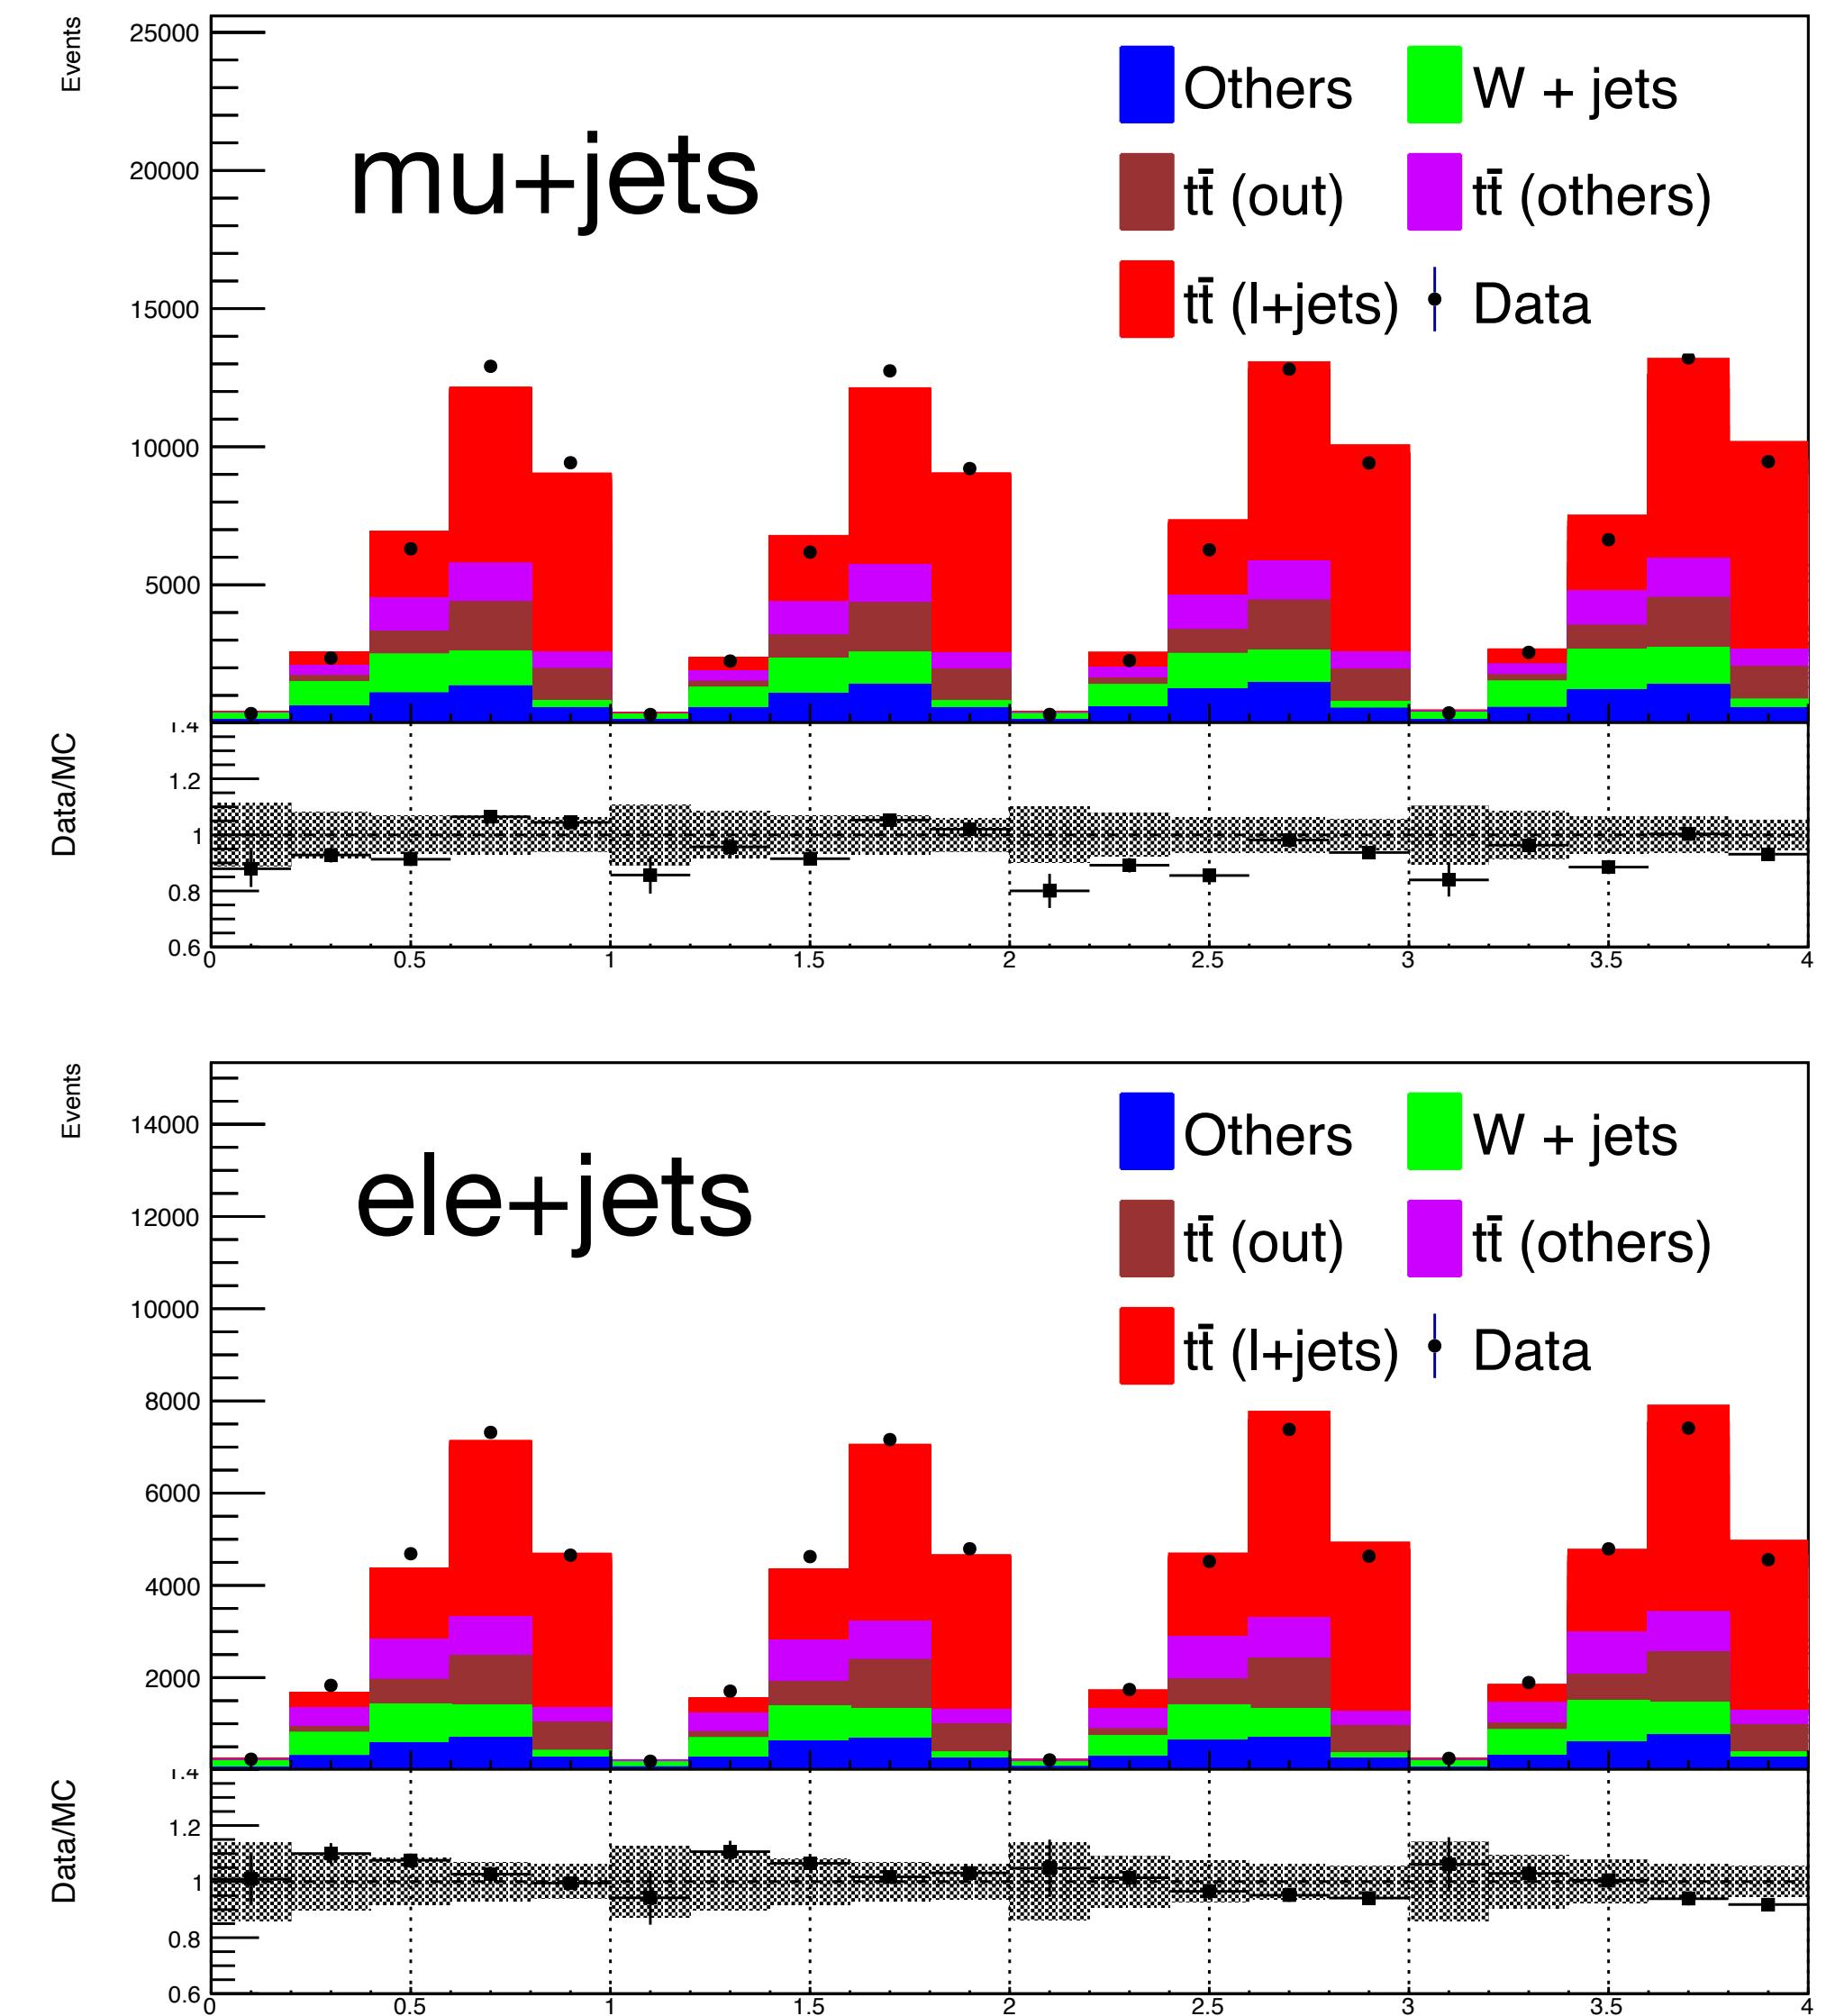

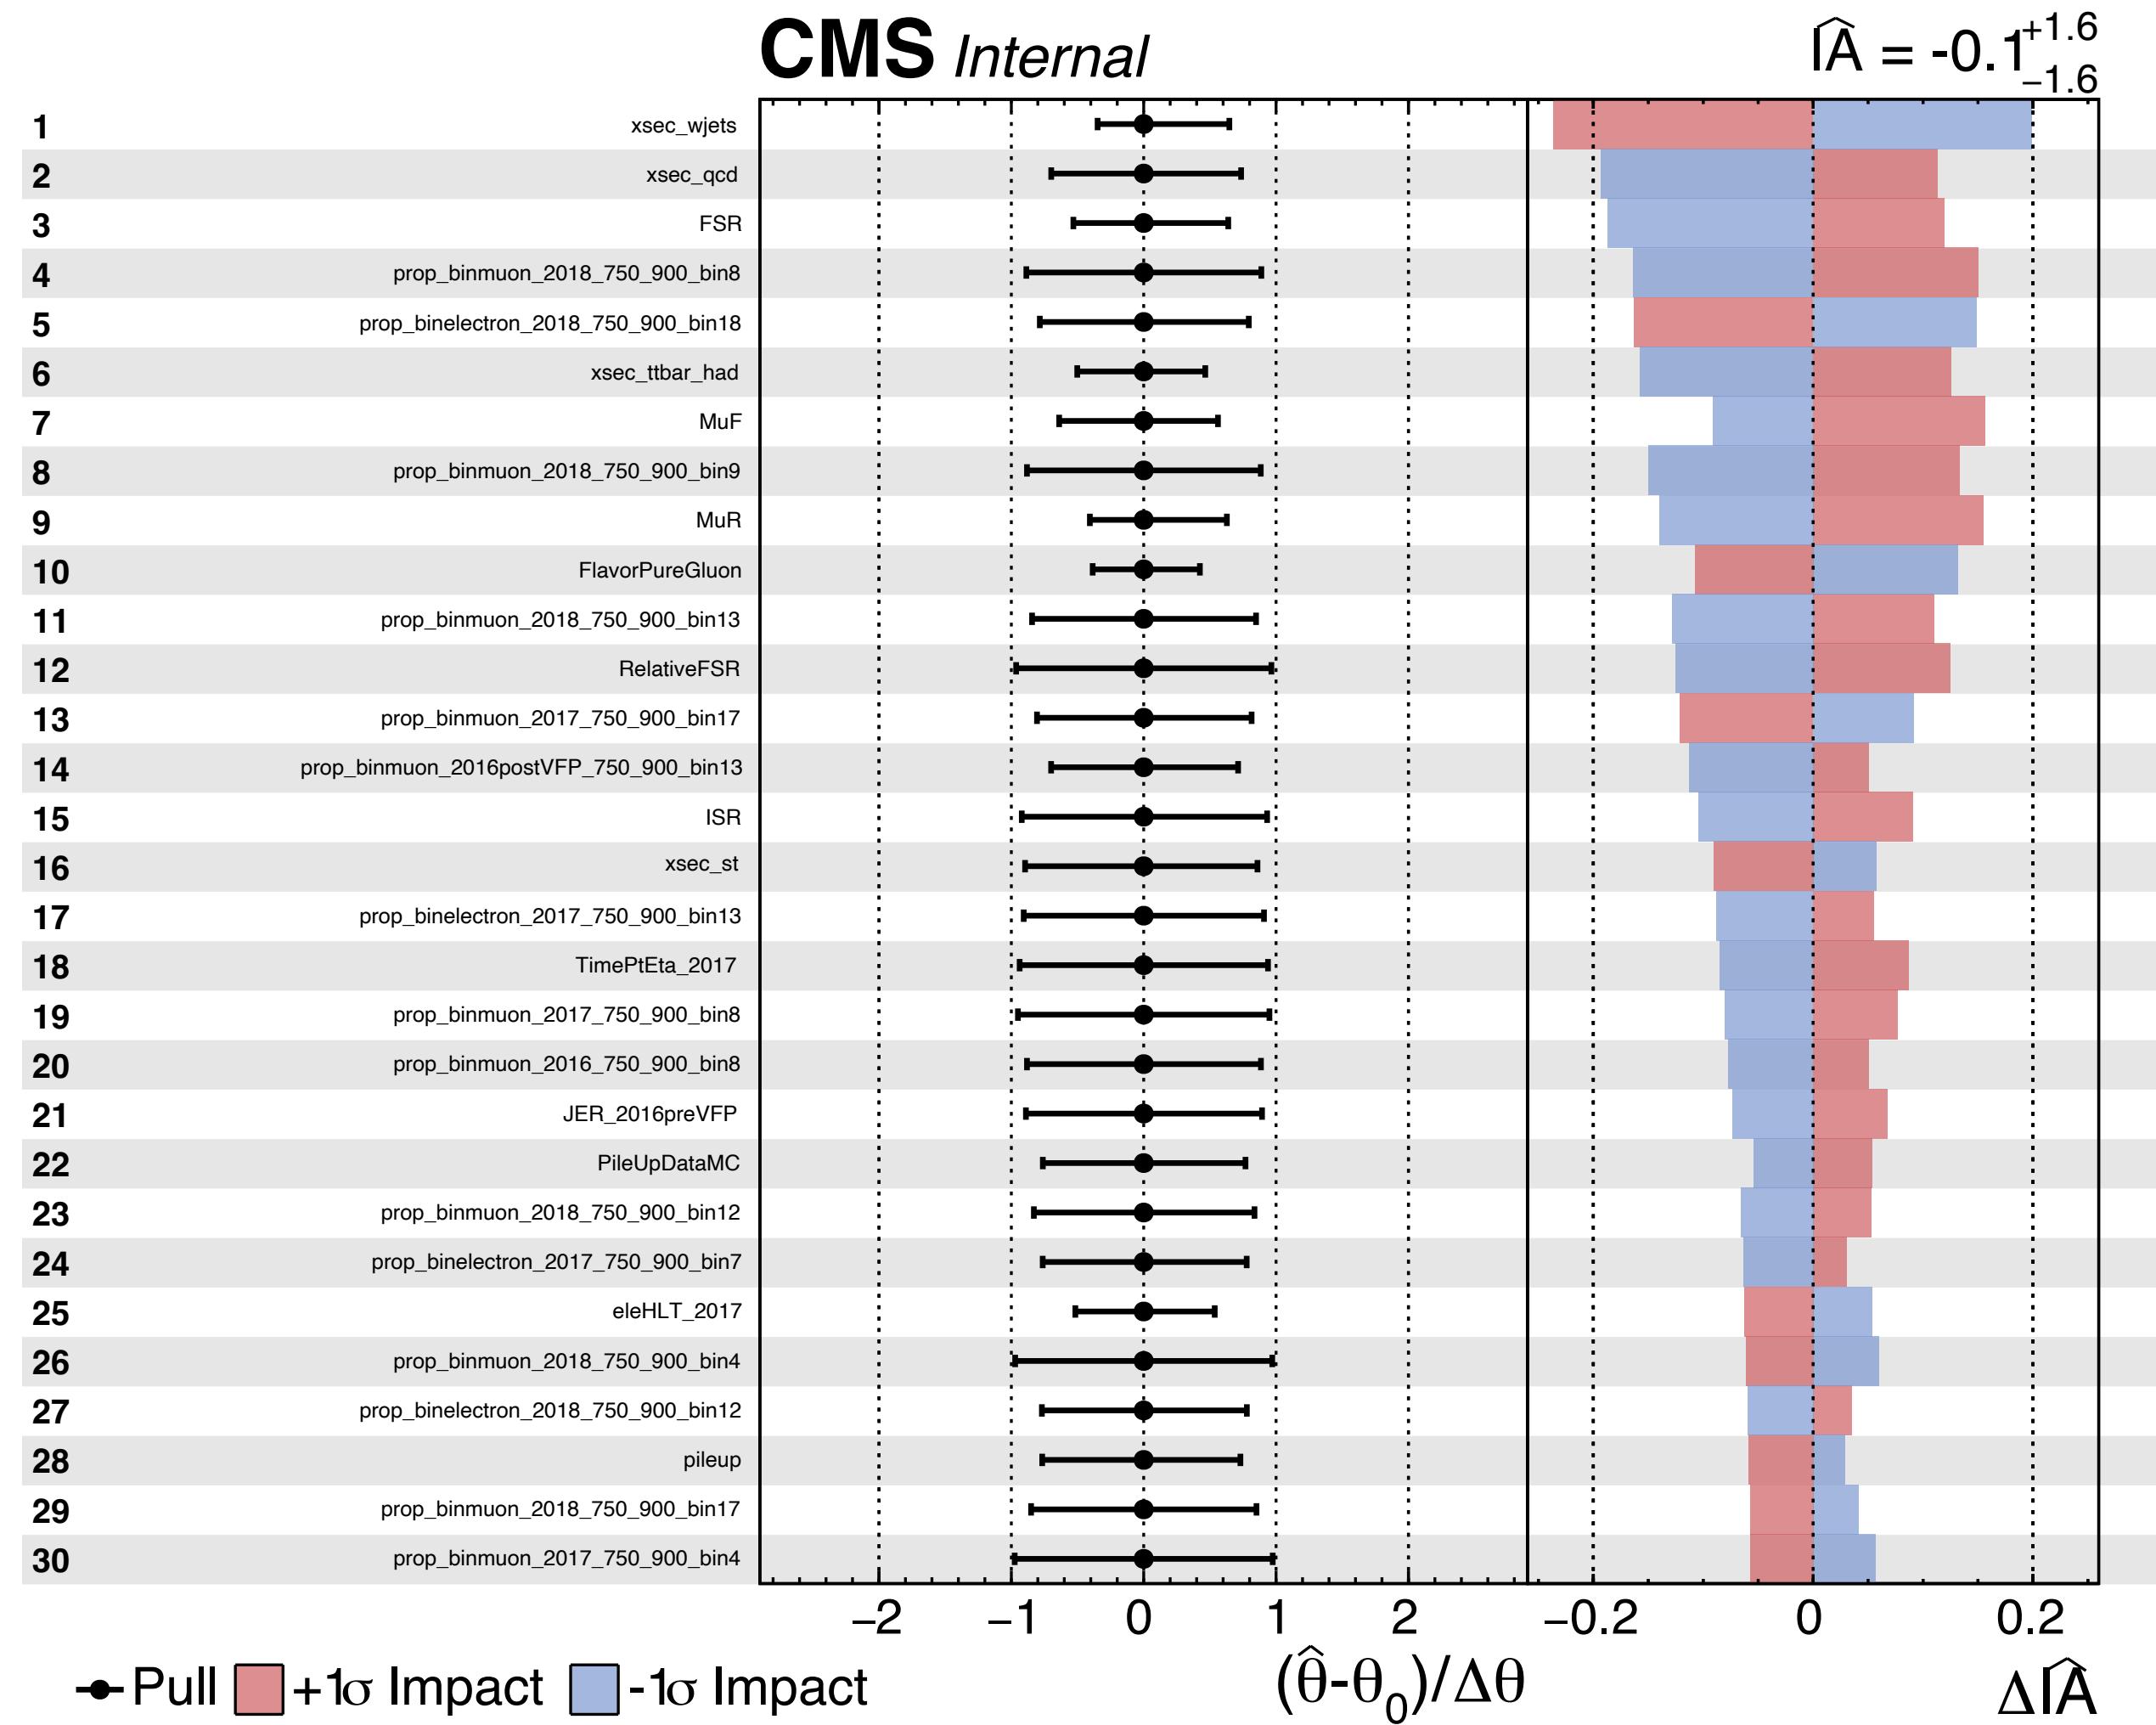

New blinded results (A_E)

FSR up/down distributions: Except for 2016 postVFP (where the effect is small but not negligible), there is generally no overlap, so the effect is not caused by statistical fluctuations.

After the changes, the nuisance parameter `xsec_st` remains high, dropping from 2nd to 7th after reducing the uncertainty from 30% to 15%. ATLAS quotes 5%, but that's for an inclusive measurement and they are a boosted regime, which I think isn't entirely correct. I prefer keeping it at 15% to account for potential mismodelings in my phase space.

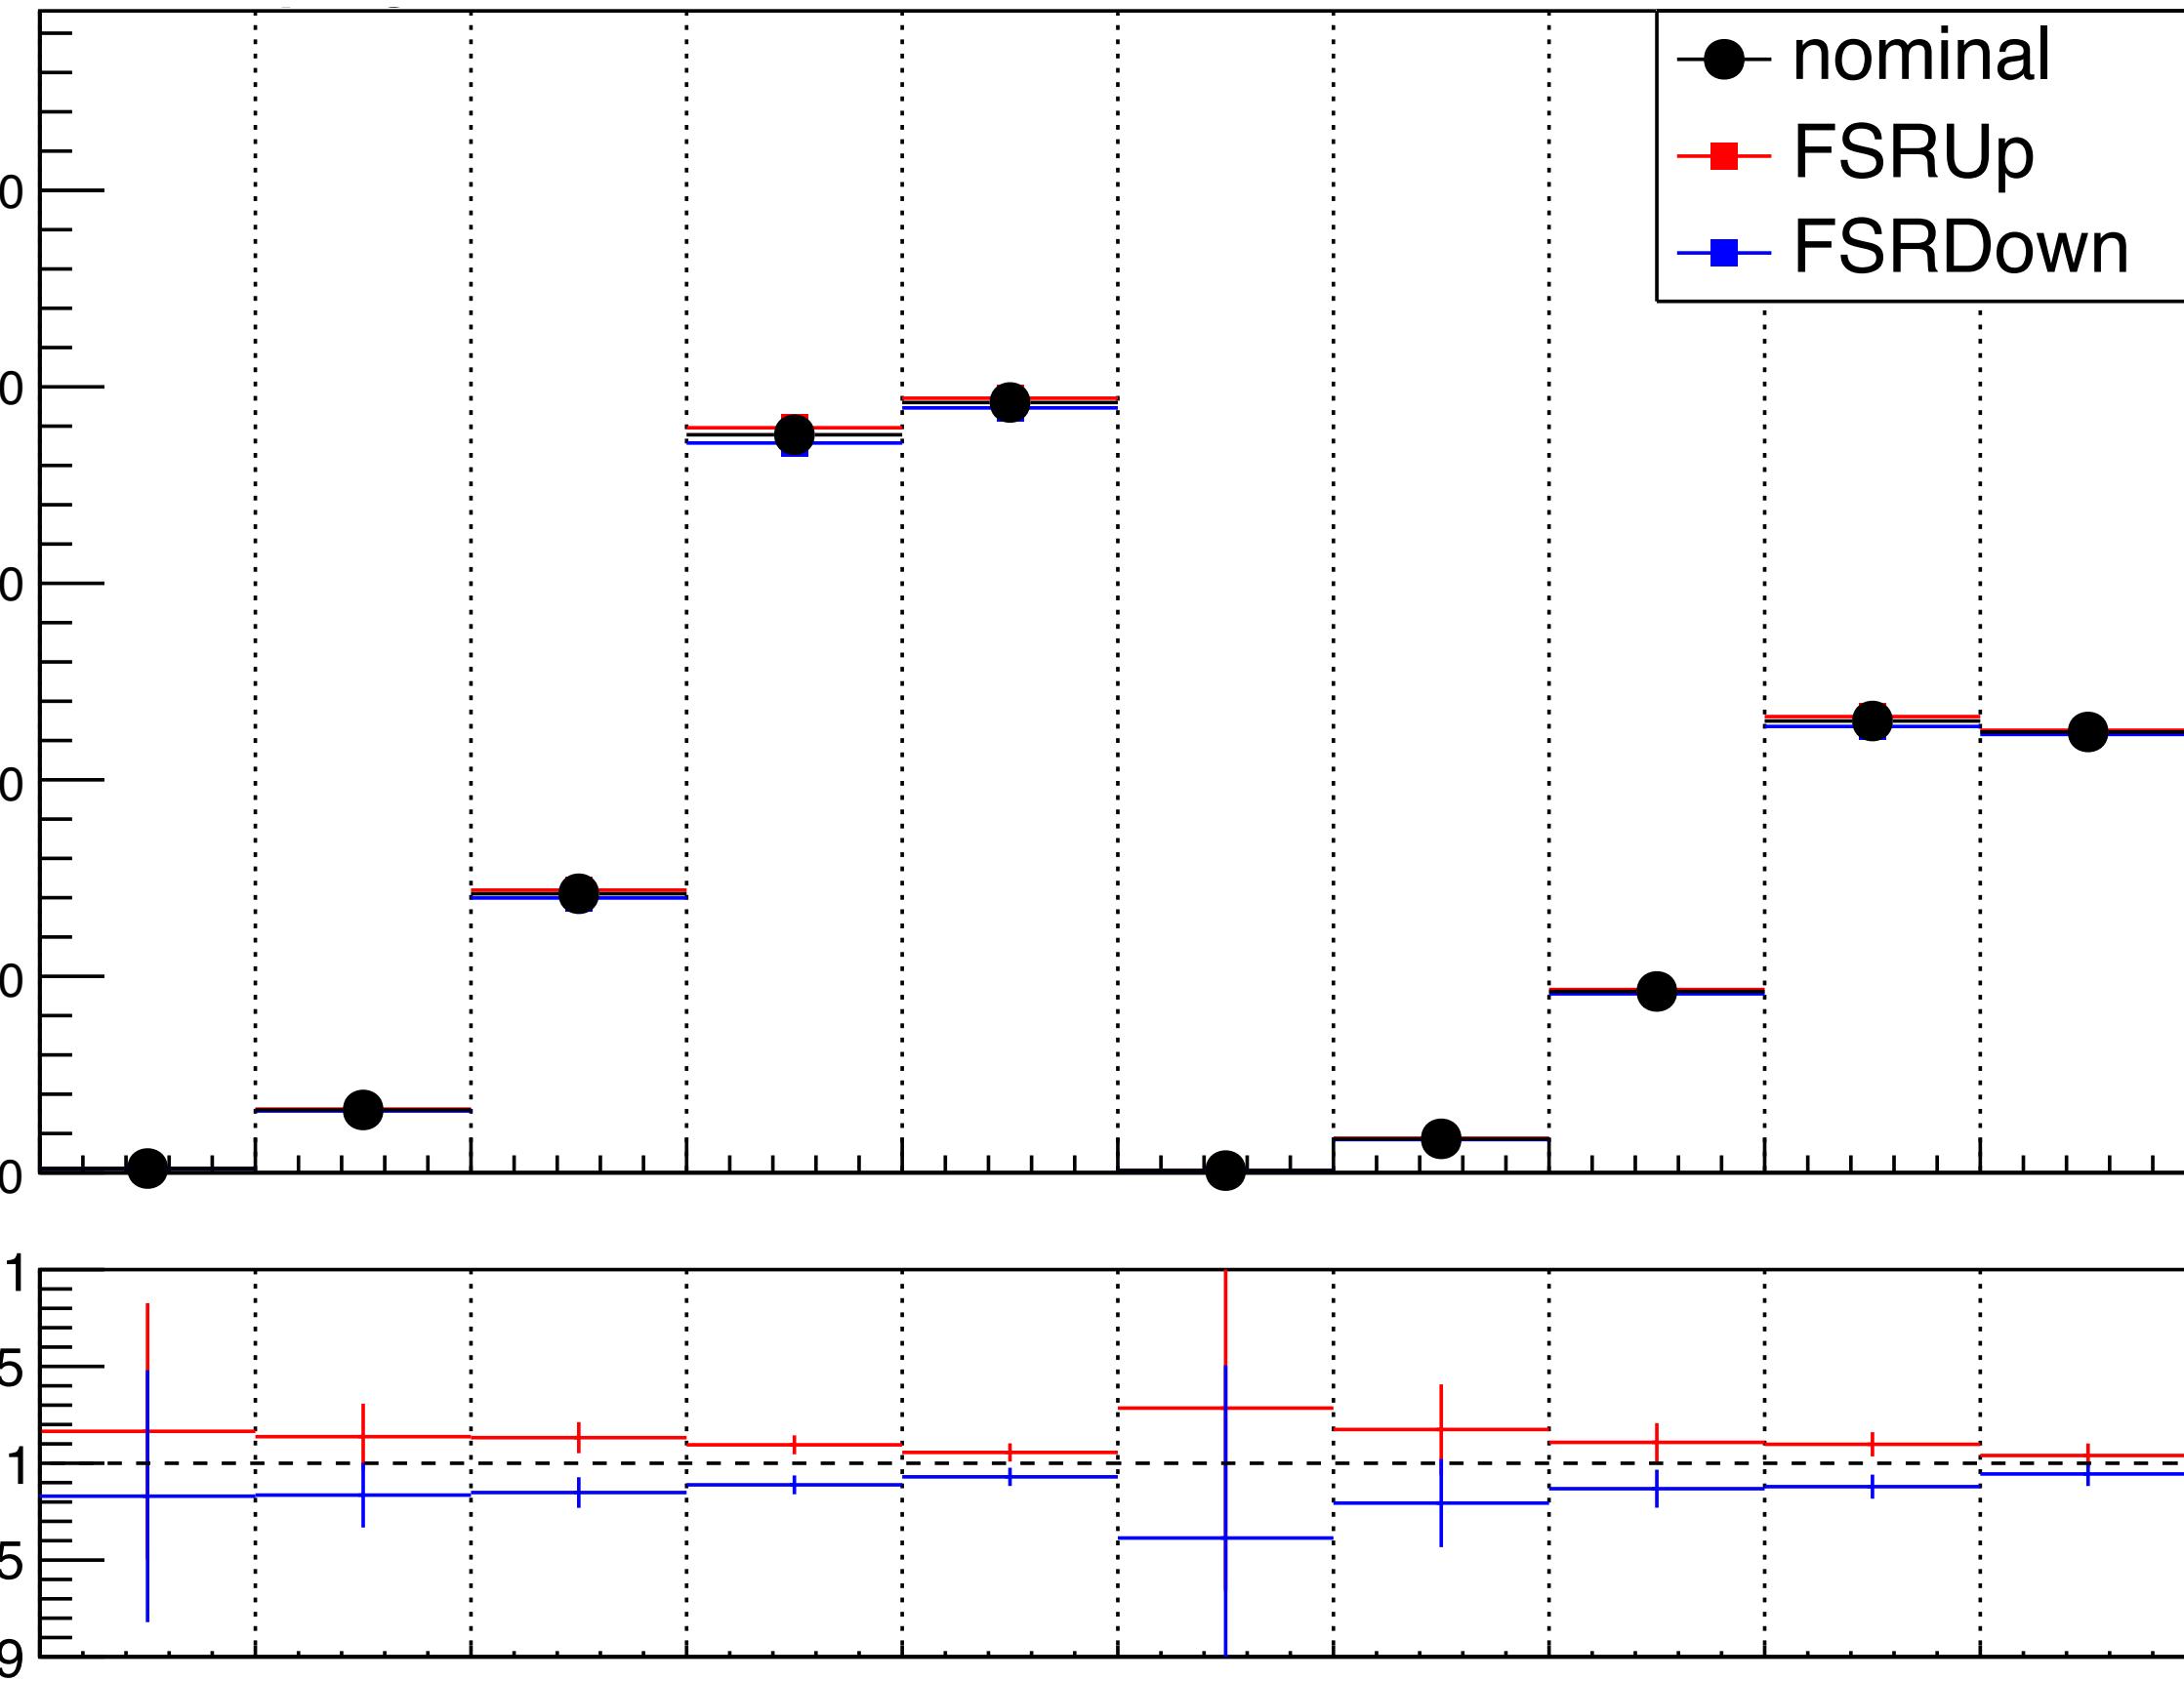

*In the new version of the AN and paper, asymmetries are reported as %
