Outline

- Cosmic rays
 - A brief history of Cosmic rays
 - Open questions
- 2 Energy Spectrum
- 3 Pierre Auger Observatory
- 4 Mass composition
- Energy loss length
- 6 Anisotropies
- 7 Aim of Thesis

Cosmic Rays

- Cosmic rays are highly energetic particles that propagate through the universe interacting with magnetic fields, gas and radiation
- \blacksquare At low energies, these ionized nuclei are mostly protons and $\alpha\text{-particles}$
- \blacksquare A fraction of them have ultra relativistic energies up to 10^{20}eV

Open questions

- The origin and the acceleration mechanisms of the production of UHECR's remain a mystery
- The key observables for addressing these questions are:
 - 1. Energy spectrum
 - 2. Mass composition
 - 3. Arrival directions

Energy Spectrum

- Energy spectrum ranges from 10⁹ eV to more than 10²⁰ eV
- It follows a power law spectrum as $F^{-\gamma}$
- Important features of the power law spectrum are:
 - **1.Knee:** Change of slope at 3×10^{15} eV
 - **2.** Ankle: Change of slope at 5×10^{18} eV

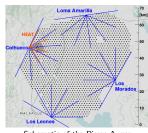

The Cosmic-Ray Energy Spectrum

(C. Evoli, DOI:

10.5281/zenodo.4396125)

- The largest UHECR Observatory in the world, located in Argentina
- The total exposure exceeds 100,000 km² sr yr
- The detectors covers an area of around 3.000 km²
- During Phase I, the observatory had two main detectors:
 - 1. Surface Detector (SD)
 - 2. Fluorescence Detector (FD)
- It underwent an upgrade called AugerPrime that includes new detectors

Schematic of the Pierre Auger Observatory array

(A. Aab et al., DOI:

10.1016/j. astropart phys. 2017.09.001)

Hybrid Detection

Surface Detector (SD)

- Consists of 1,660 water-Chereknov detector tanks
- Each tank is spaced at 1.5 kilometers with respect to each other

Photograph of an SD station

Fluorescence Detector (FD)

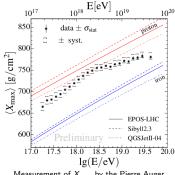

- Consists of 27 fluorescence telescopes
- These are distributed into four different stations with six at each location

Photograph of the Los Morados FD station

Mass composition

- UHECR's consist of many atomic nuclei species, ranging from protons to iron nuclei
- For lower energies, lighter elements are more abundant in cosmic rays
- Pierre Auger Collaboration has found evidence that the composition becomes heavier for higher energies

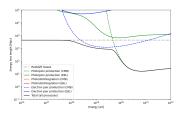

Measurement of X_{max} by the Pierre Auger Observatory

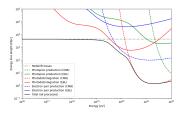

(A. Yushkov et al., DOI: 10.22323/1.358.0482)

Energy loss length

 During the extragalactic propagation, CR's interact with the photon background mainly the CMB and EBL

Energy loss lengths for proton

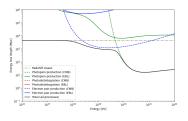

Energy loss lengths for Iron-56

 Pair production, photo-pion production and photodisintegration play an important role in the modification of the nuclear species of CR's

Energy loss length

 In case of a pure proton composition, photo-disintegration would not be possible

Energy loss lengths for proton

Energy loss lengths for Iron-56

■ In the case of Iron-56, pion production is shifted towards higher energies as compared to the case of protons

Anisotropies

In 2017, first detection of large-scale anisotropy in UHECR arrival directions at 5.2σ significance was made

Sky map in equatorial coordinates showing the cosmic-ray flux above 8 $\ensuremath{\text{EeV}}$

(A. Aab et al., DOI: 10.1126/science.aan4338)

- 32,187 cosmic ray events above 8 EeV were analyzed
- Ultra-high-energy cosmic rays above 8 EeV show clear anisotropy
- It provides strong evidence for extragalactic origin

Aim of Thesis

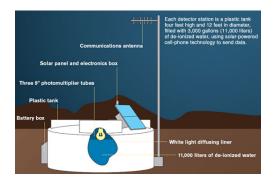

- We aim to use CRPropa¹ to simulate the propagation of CR's at energies above 8 EeV
- We plan to consider the effect of cosmic magnetic fields and take into account all relevant interactions
- We intend to simulate composition dependent anisotropies for a range of astrophysical scenarios using CRPropa
- Finally, we will compare such predictions with the data from the Pierre Auger experiment and explore what kind of constraints on astrophysical scenarios can potentially be derived
