

# Polarimetry: Prototype Design for the Cherenkov Detector

Daniela Käfer  
daniela.kaefer@desy.de

Workshop on Polarization and Energy Measurements  
Berlin-Zeuthen – April 9-11, 2008

- 1 Cherenkov Detector Prototype
  - How does it look like?
  - Testbox: Concept & Prototype Design
  
- 2 Another Testbeam Period
  - Where? ... and what for?
  - Planning the procedure
  
- 3 Summary & Outlook

# Upstream Polarimeter: Cherenkov Hodoscope

- scatter & deflect  $\approx 10^3$  electrons/bunch
- the Compton edge is always at the same spot in the Cherenkov detector
- spectra are indep. of beam energy

# The Cherenkov Detector I

How it could look like in the ILC:

- beam stay clear of 2 cm of the beam pipe
- **tapered beam pipe** with thin exit-window to avoid the creation of wake fields as much as possible ...
- **staggered aluminum channels** (U-shaped pipes)
  - ★ one end occupied by an LED for calibration purposes
  - ★ the other end equipped with a photodetector
- each aluminum channel equipped with its own gas system  
(still needs a lot of design & engineering work)

# The Cherenkov Detector II

# Testbox: Concept & Design

- aluminum box with **two channels**
- thin walls of 0.5 mm (maybe even 0.3 mm)
- thin entrance (and exit) window
- flanges for a calibration system (LED-housing or laser) and for photodetector modules (quick & easy exchange)
- entire box flooded with gas (most likely:  $C_4F_{10}$ )
- thin bottom side ( $\approx 1$  cm) for setup @ELSA in Bonn...

# ... want Testbox with 3 Channels

Why three channels & two flanges? ... to study:

- different photodetectors at once
- **crosstalk** between channels
- different readout modes, depending on photodetectors, e.g. multianode photodetectors (see talk by C. Helebrant)
- **different calibration systems**, i.e. either via LED- or laser-light (housing or thin throughput window)
- effect of wall thickness / beam spread ...

# Some Simulated Events I

## Simulation of the testbox:

- 3 channels of polished aluminum
- thin entrance window (Al so far, might be changed)
- the photodetectors are **not simulated in GEANT**;

choose a modular setup (e.g. ROOT macros) to be able to quickly exchange different photodetectors

vacuum chamber filled with  $C_4F_{10}$

## Some Simulated Events II

one  $e^-$   
incident

two  $e^-$   
incident

vacuum chamber filled with  $C_4F_{10}$

# Advantages of U-shaped Channels I

- no synchrotron radiation incident on the photodetectors
- **no (or much less) crosstalk** between different channels (compared to a layout in the x/z-plane)
- only  $\approx 2-3$  reflections  
→ reflectivity does not have to be extremely good (e.g. 92-94% sufficient)

# Advantages of U-shaped Channels II

Comparison: **U-shaped testbox** versus **planar SLD-layout**

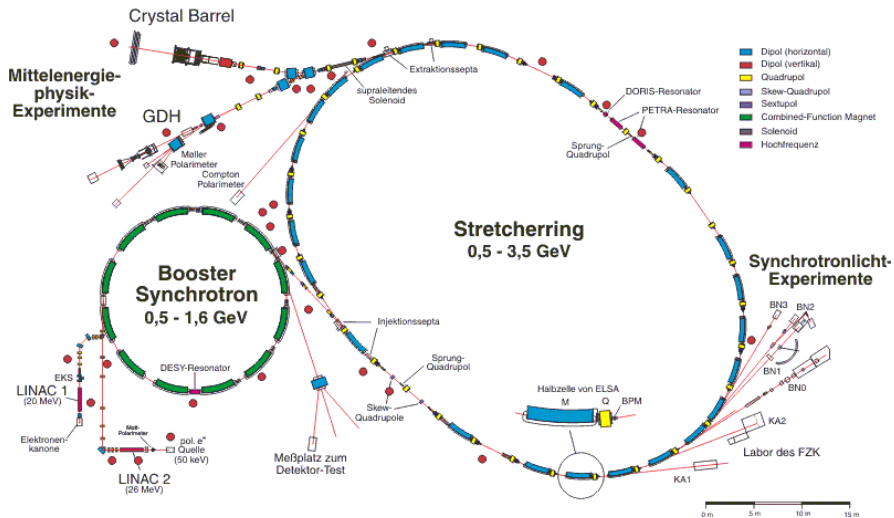

⇒ no, or at least, largely reduced crosstalk !

# Testbeam at ELSA

# ELSA: Elektronen-Stretcher-Anlage

# View of the ELSA experimental area

## Why @ ELSA ?

- because the DESY-testbeam is tertiary → very low rate, only single electrons
- @ELSA: **higher rates** (10-100 nA, maybe 1000 nA)
- more electrons, not just single electron events
- **but** energy still only about 3 to 3.5 GeV
- will do thorough simulation studies & LED-tests before moving the testbox to ELSA.

# Possible Testbeam Setup

Might operate parasitic to other testbeam users...

- but need new/different beam dump @ ELSA
- probable placement right after beam extraction
- parasitic user due to small size of the actual testbox
- When? - early next year (winter/spring 2009)

# Testbox Setup & Support

To allow parasitic testbeam time together with other experiments:

- install testbox right after the beam extraction  
(on top of a block of concrete, where the electron beam is bent down and dumped when a photon beam is used afterwards)
- thus: need very flat support table  
(movable in x- and y-directions)
- thin entrance and exit windows to reduce beam scatter and synchrotron radiation (radiation safety issues)

# Summary & Outlook

# Summary & Outlook

- Conceptual design for the testbox is ongoing
- Testbox construction planning has also started  
(will most likely be built using resources at Uni-HH)
- Simulation studies of testbox and ILC-prototype are ongoing
- Proposal for testbeam time (schedule) @ELSA written  
(hoping to hear some good news soon)
