

# SNR estimation using fixed shaping time extracted from synchronous data

Eliza Teodorescu

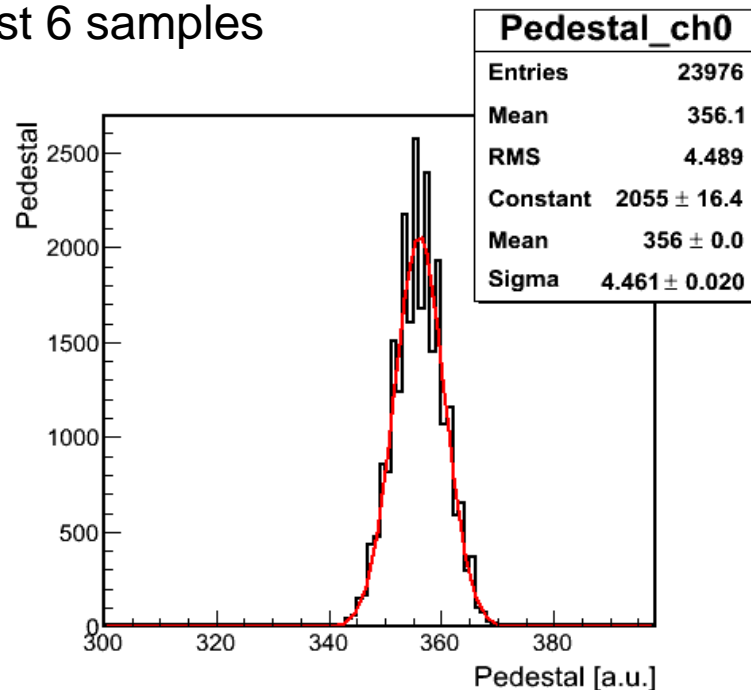

Tau plot – fixed to 44.92 ns (from synchronous data)

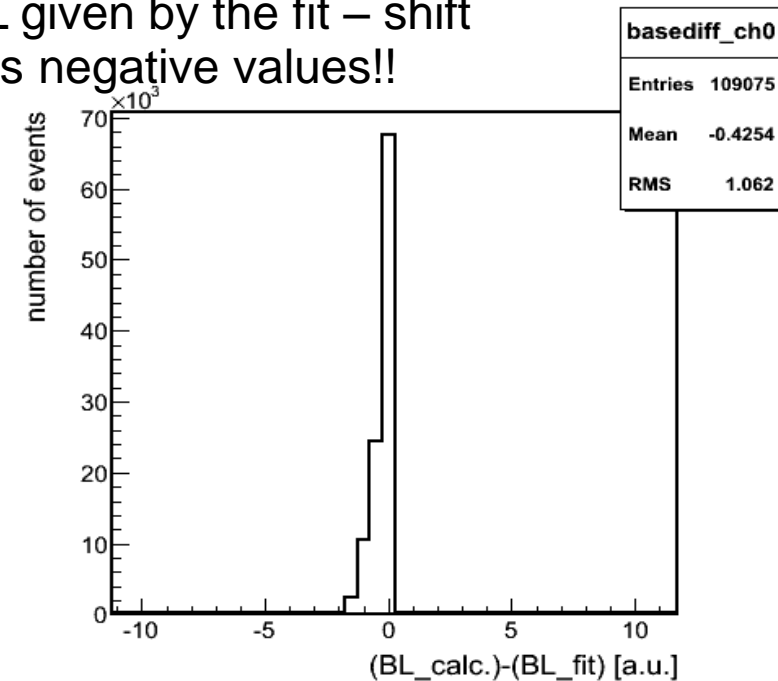

Integration window ~300 ns

Pedestal distribution – integrated over the first 6 samples

Difference between calculated BL and BL given by the fit – shift towards negative values!!

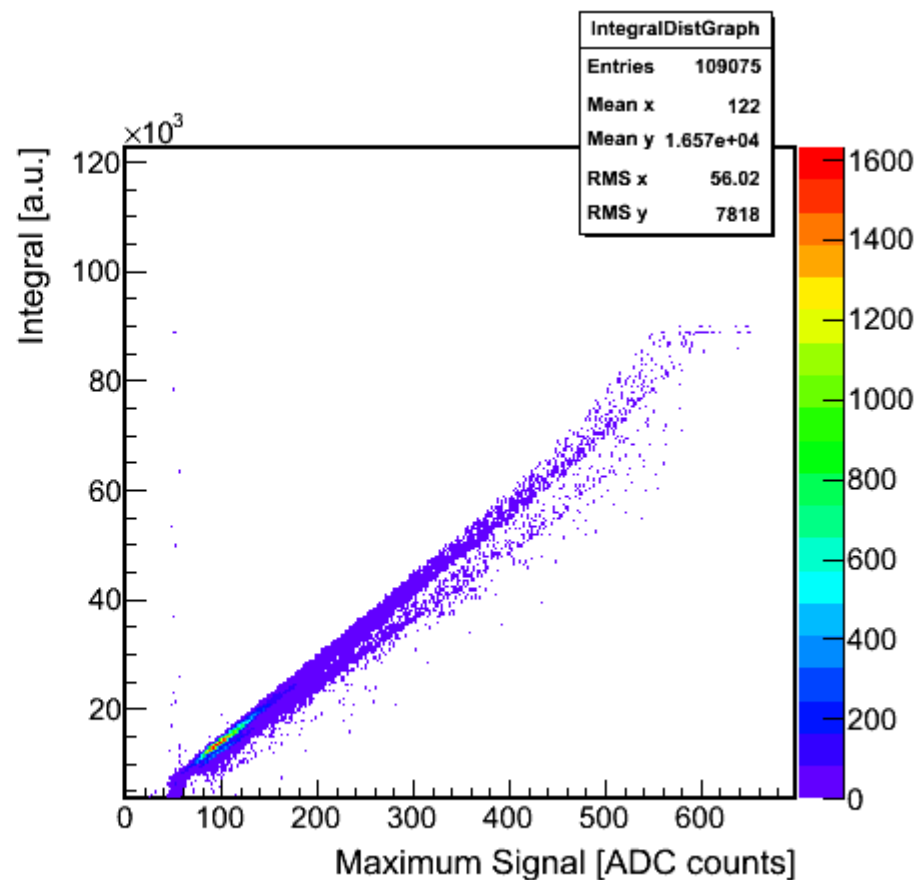

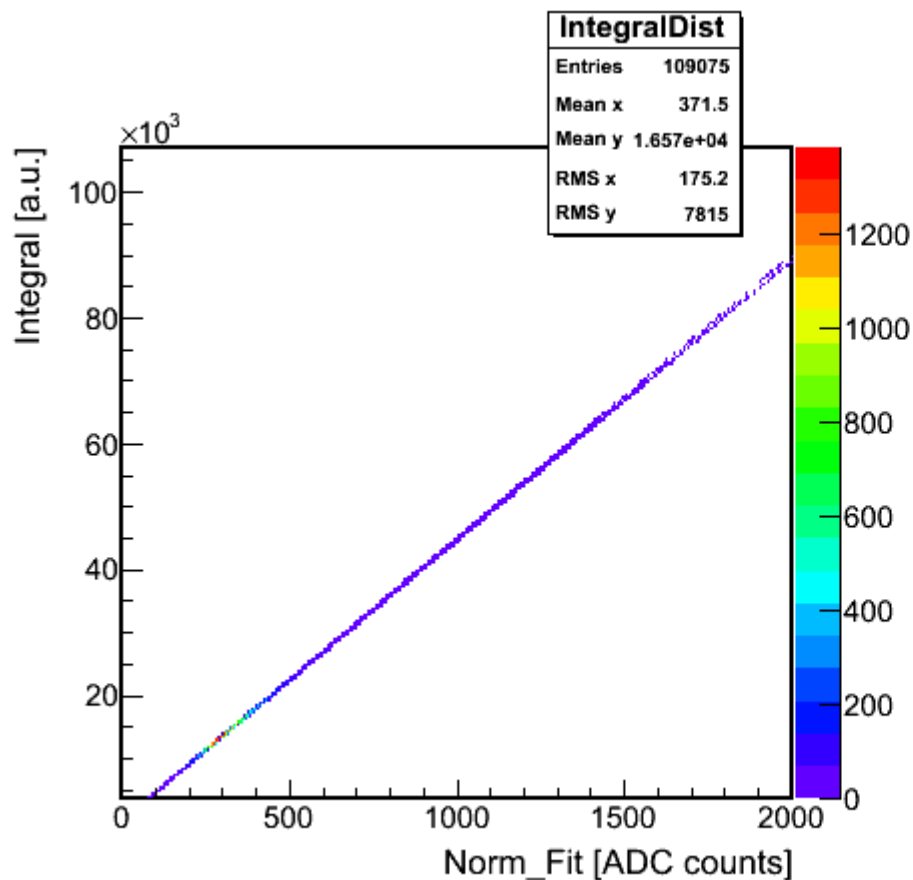

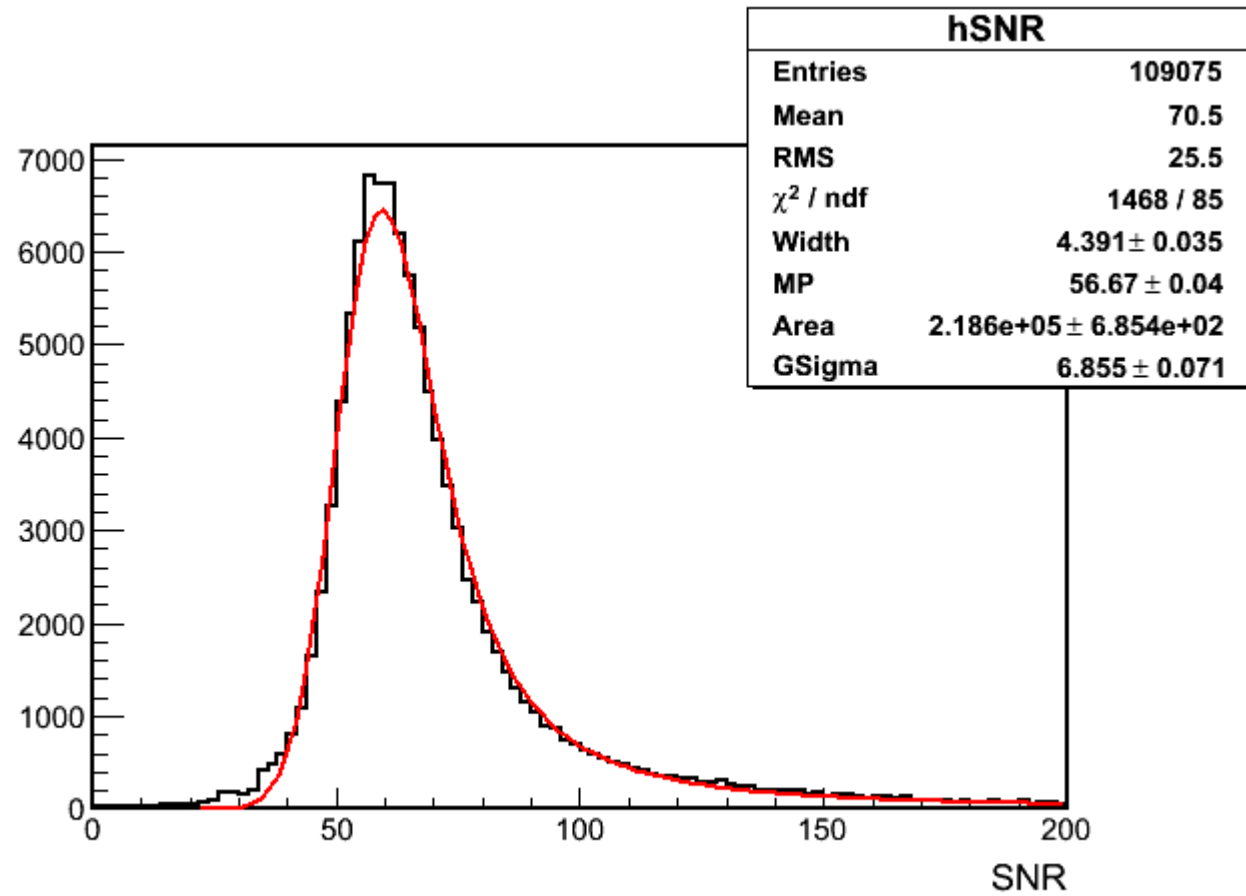

## Correlations between the integral and the amplitude

Left: amplitude is given by the fit

Right: amplitude is extracted directly from data

Integral is calculated in the 300 ns integration window

SNR = 56.67

**MPV\_Signal\_Size (Area) = MPV\_Norm\* $\tau$**   
**=  $286 \times 44.92 = 12847.12$  ADC\_counts\*ns**  
**=  $256.94$  ADC\_counts\*sample**

**SNR =  $256.94 / 4.461 = 57.6$**

**MPV\_Integral (Area) =  $12780$  ADC\_counts\*ns**  
**=  $255.6$  ADC\_counts\*sample**

**SNR =  $255.6 / 4.461 = 57.3$**
