

Tracking reconstruction, edge effects and cross-talk

Veta Ghenescu, Titi Preda

Track reconstruction methodology

1. Tracking:

- DigXs and DigYs have been took for all telescope planes
- Hits number/plane = 1
- Reconstruction of the track – has bee done so that the residual to the measured points (x_1, y_1, z_1) , (x_2, y_2, z_2) and (x_3, y_3, z_3) is minimum (track reconstruction method is an approximate one). Sigma from fits are smaller than about $30\mu\text{m}$
- The Si chamber alignment was make with a maximum 100microns shift

2. Signal:

- Condition for signal (already used in precedent analysis):
 $\text{MAXC}(\text{pad_nr}) > \text{Eped}(\text{pad_nr}) + \text{coef} * \text{RMS}(\text{pad_nr})$, we used $\text{coef} = 3$

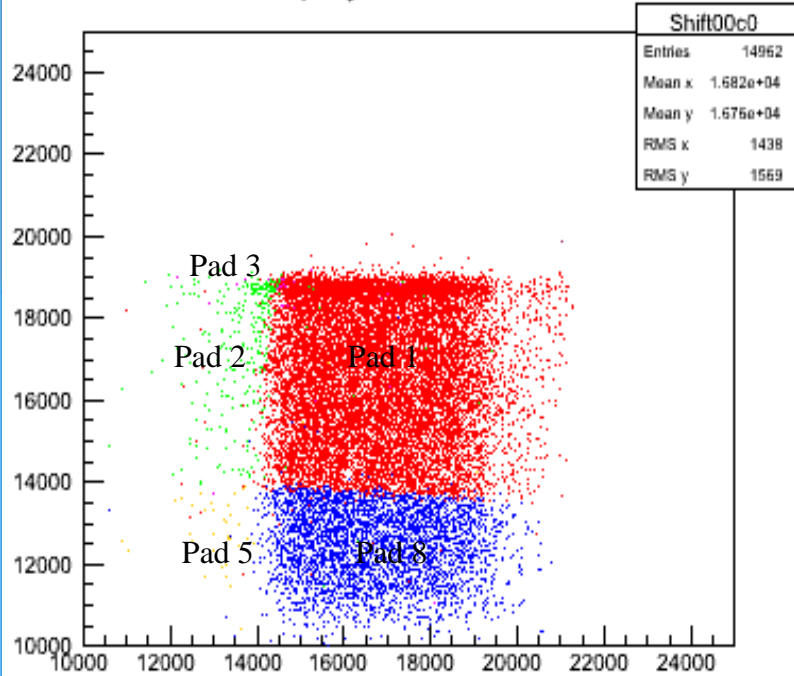

I. Merging data from FCAL data acquisition and TelAna output

I.1. Methodology:

1. Each trigger with hits number = 1 is characterized by 2 vectors:
 - a. (X, Y) – track intersection with sensor
 - b. $(S_{p1}, S_{p2}, \dots, S_{pn})$ with $n > 0$ and $S_{p1} \geq S_{p2} \geq S_{p3} \dots$, where S_{ps} are the Signals in pads $p1, p2, \dots, pn$ in ADC Channels;
2. We map (X, Y) coordinates to the pad $p1$ with the biggest Signal;
3. We have assumed that the biggest Signal represents dE/dX of the electron interaction with sensor. The small Signals for the same trigger, are produced due to effects like edge and cross-talk;
4. The coordinate system is given in the bellow picture.

Beam projection on Sensor

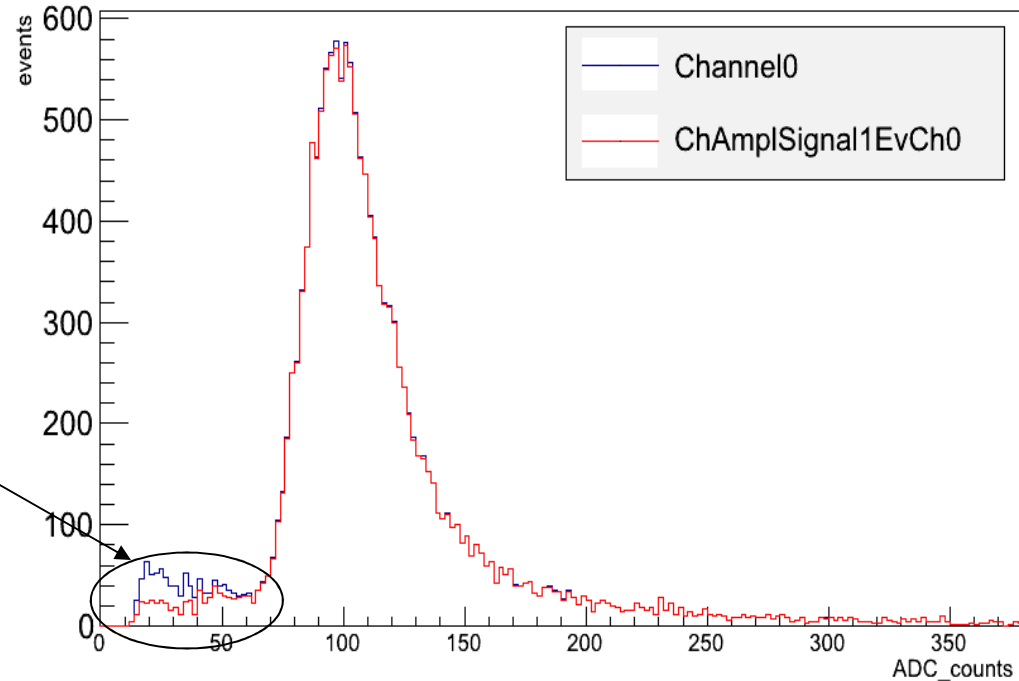

- For pads reconstruction we used only one run/pad,
- Pad 1, run 248

Edge and cross-talk effects induced in pad 1

I.2. Results

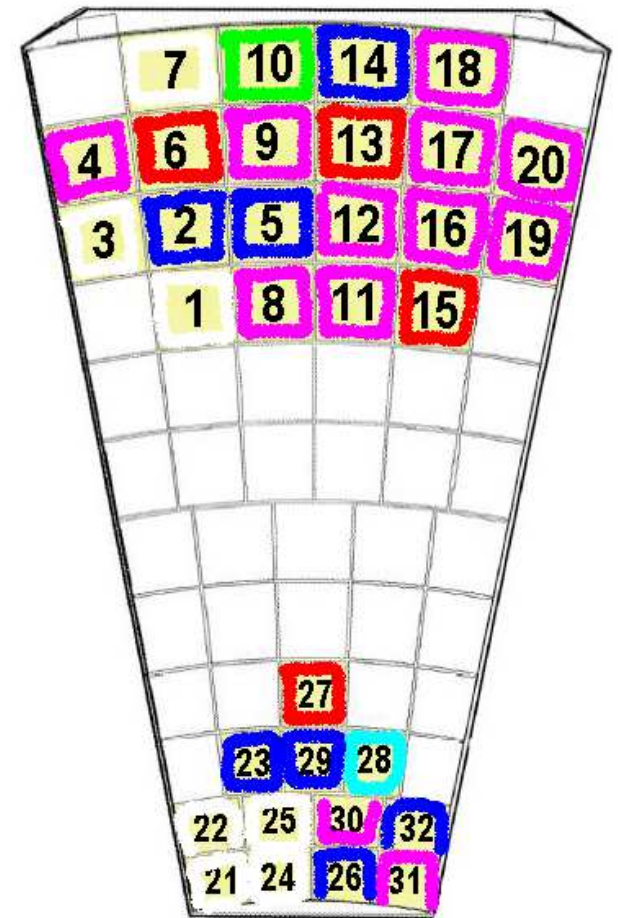

1. We represent:
 - a. (X,Y) and
 - b. Color the maximum of the $(S_{p1}, S_{p2}, \dots, S_{pn})$ vector
2. Blue Histogram represents ADC Signals for Ch0 (Pad 1) with only condition:
 $\text{MAXC}(\text{pad_nr}) > \text{Eped}(\text{pad_nr}) + 3 * \text{RMS}(\text{pad_nr})$
 It includes **signals of all orders** ($S_{p1}, S_{p2}, \dots, S_{pn}$), that means it **includes** electrons interaction with pad and also other effects (**edge + crosstalk effects**);
3. Red Histogram represents ADC **Signals** with above condition and in addition S_{p1} (**maximum signal**). It has to include only the signal produced by electron interaction with sensor;

Amplitude

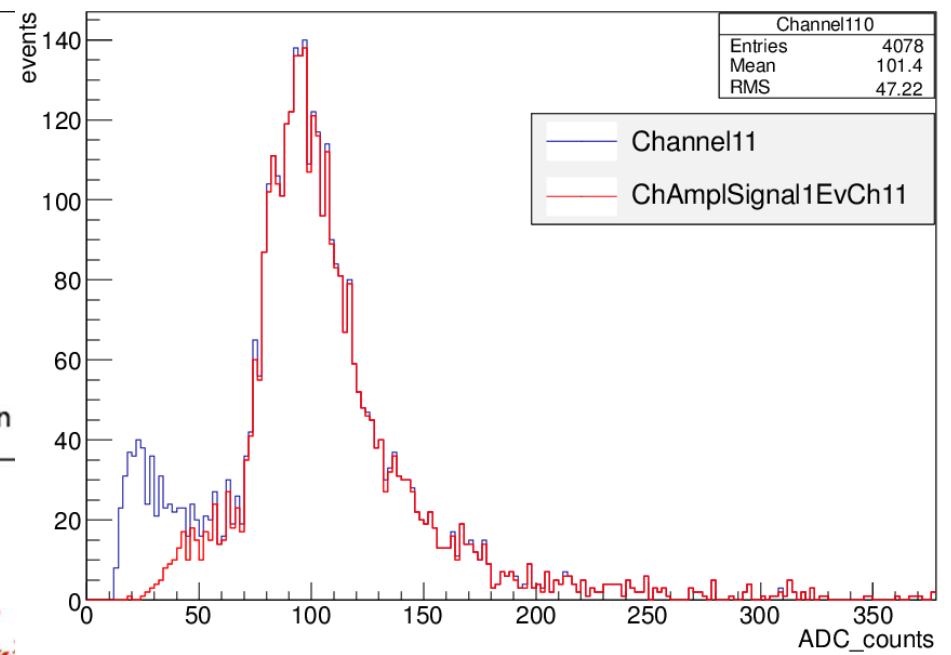

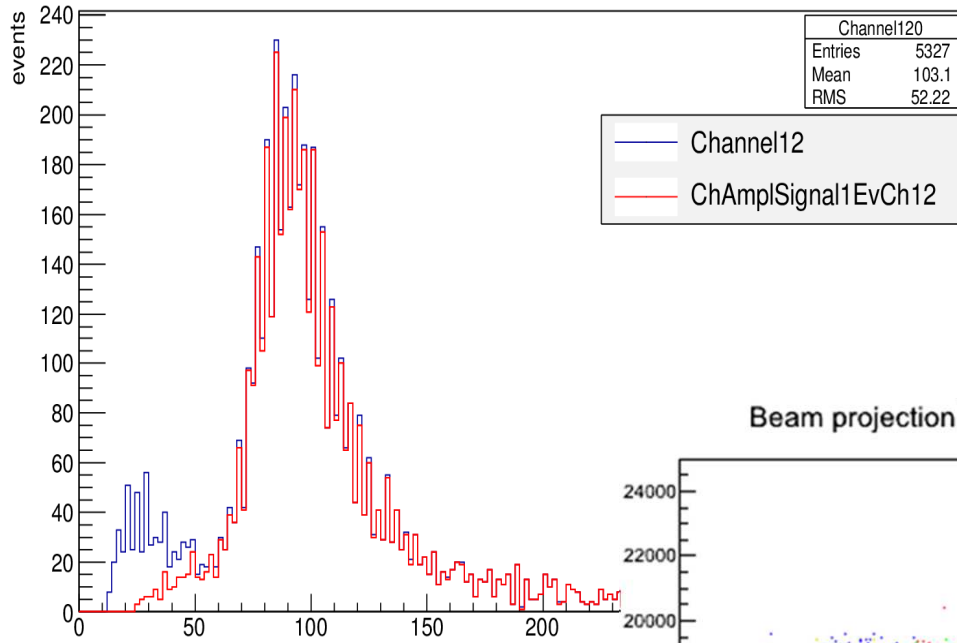

Shifts between FCAL and TelAna triggers

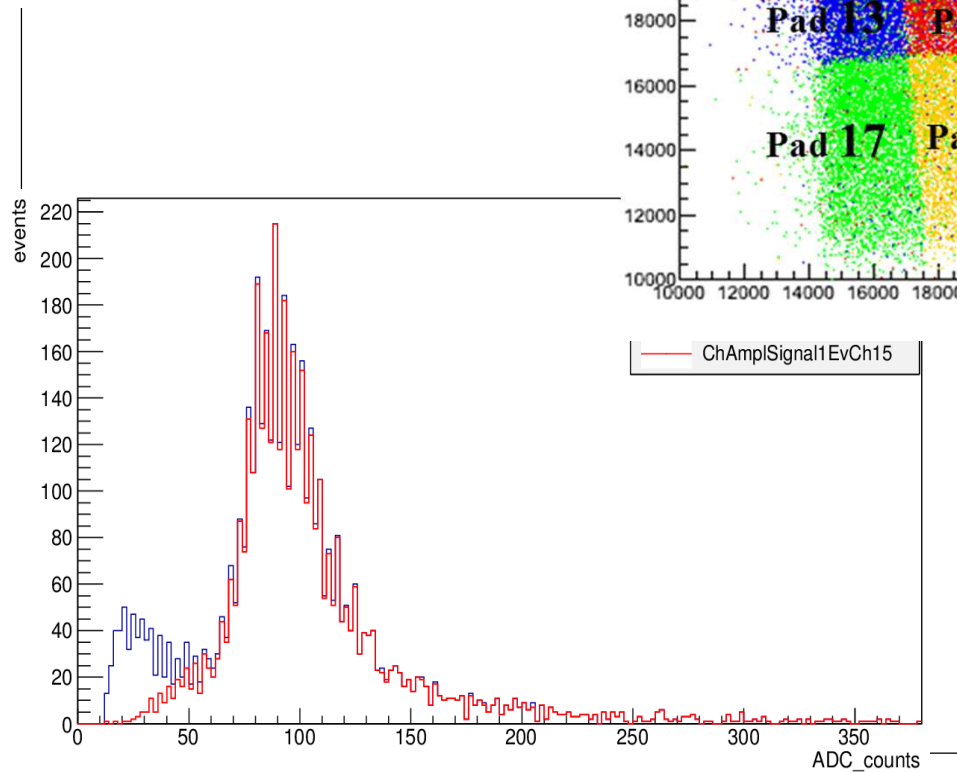

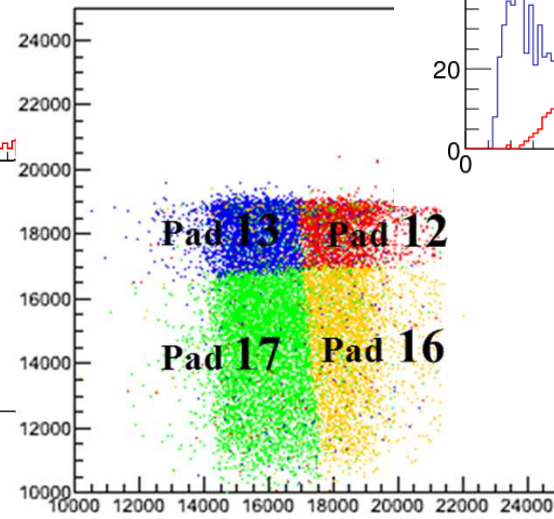

shift vs number of pads

- 11 shifts, [-5, -4, ...0 ... 4, 5], between TelAna and FCAL triggers according with Szymon methods;
- The shift effect has been studied for 50k events and for 8k events (???)

Beam projection on

Attempt for a qualitative study of edge + cross-talk effects

- Pads 12, 13, 16, 17, run 400;
- We study the effects for: $(S_{p1}-S_{p2})/S_{p1}$ from 10% to 100%;
where: S_{p1} = dE/dx signal, S_{p2} = Induced signal

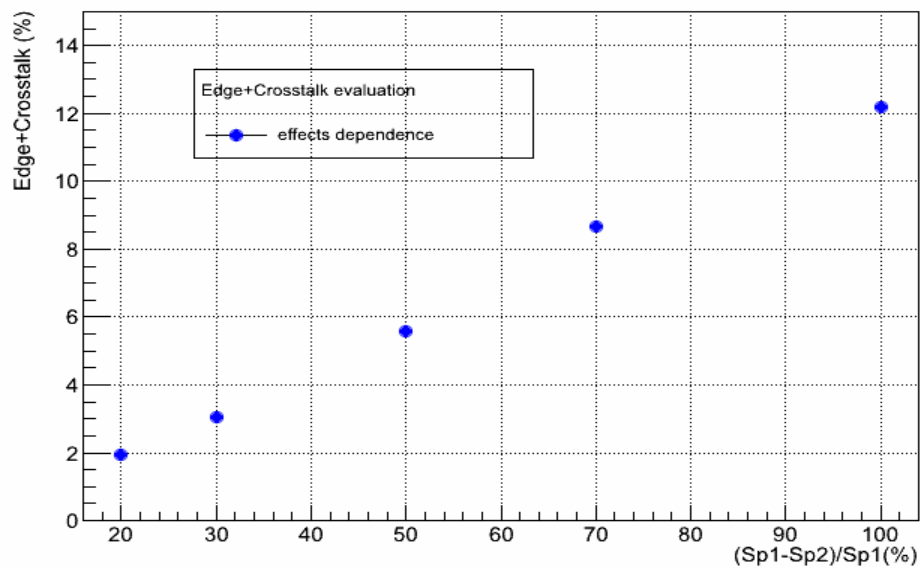

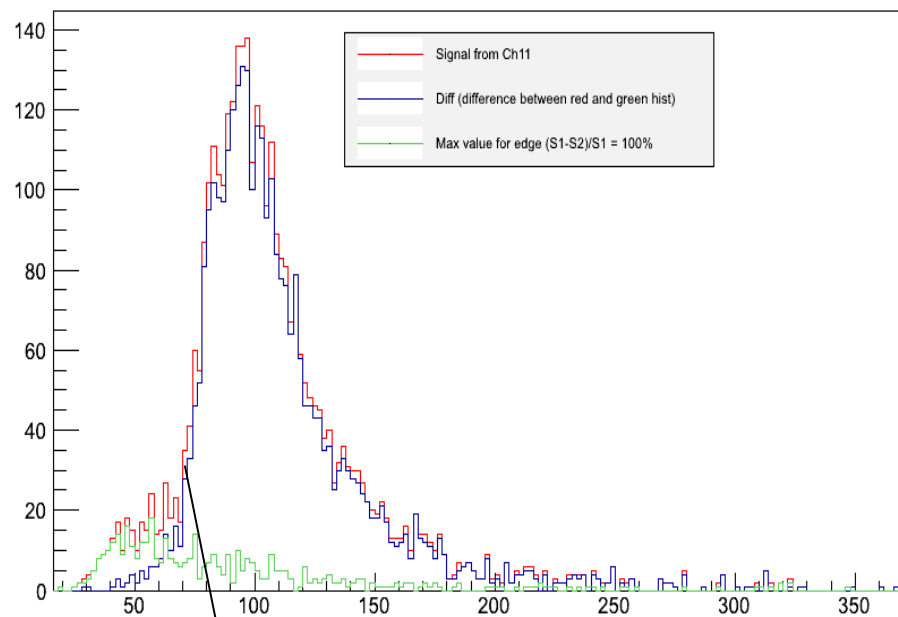

Threshold = 20;
 $(S_{p1} - S_{p2})/S_{p1} = 30\%$;

Threshold = 20;
 $(S_{p1} - S_{p2})/S_{p1} = 100\%$

Attempt for a quantitative study of edge + Crosstalk effects

Conclusions

- We developed a methodology for track reconstruction;
- We didn't find trigger shift values for some pads;
- We could see clear patterns for pads and also for edge effect;
- We found a maximum of edge effect + cross-talk of about 12% for pad 12, run 400 produced by three neighbors pad (13, 16, 17);
