

Fermi 130 GeV gamma-ray line as an indirect signal of DM

Martti Raidal

NICPB, Tallinn, Estonia

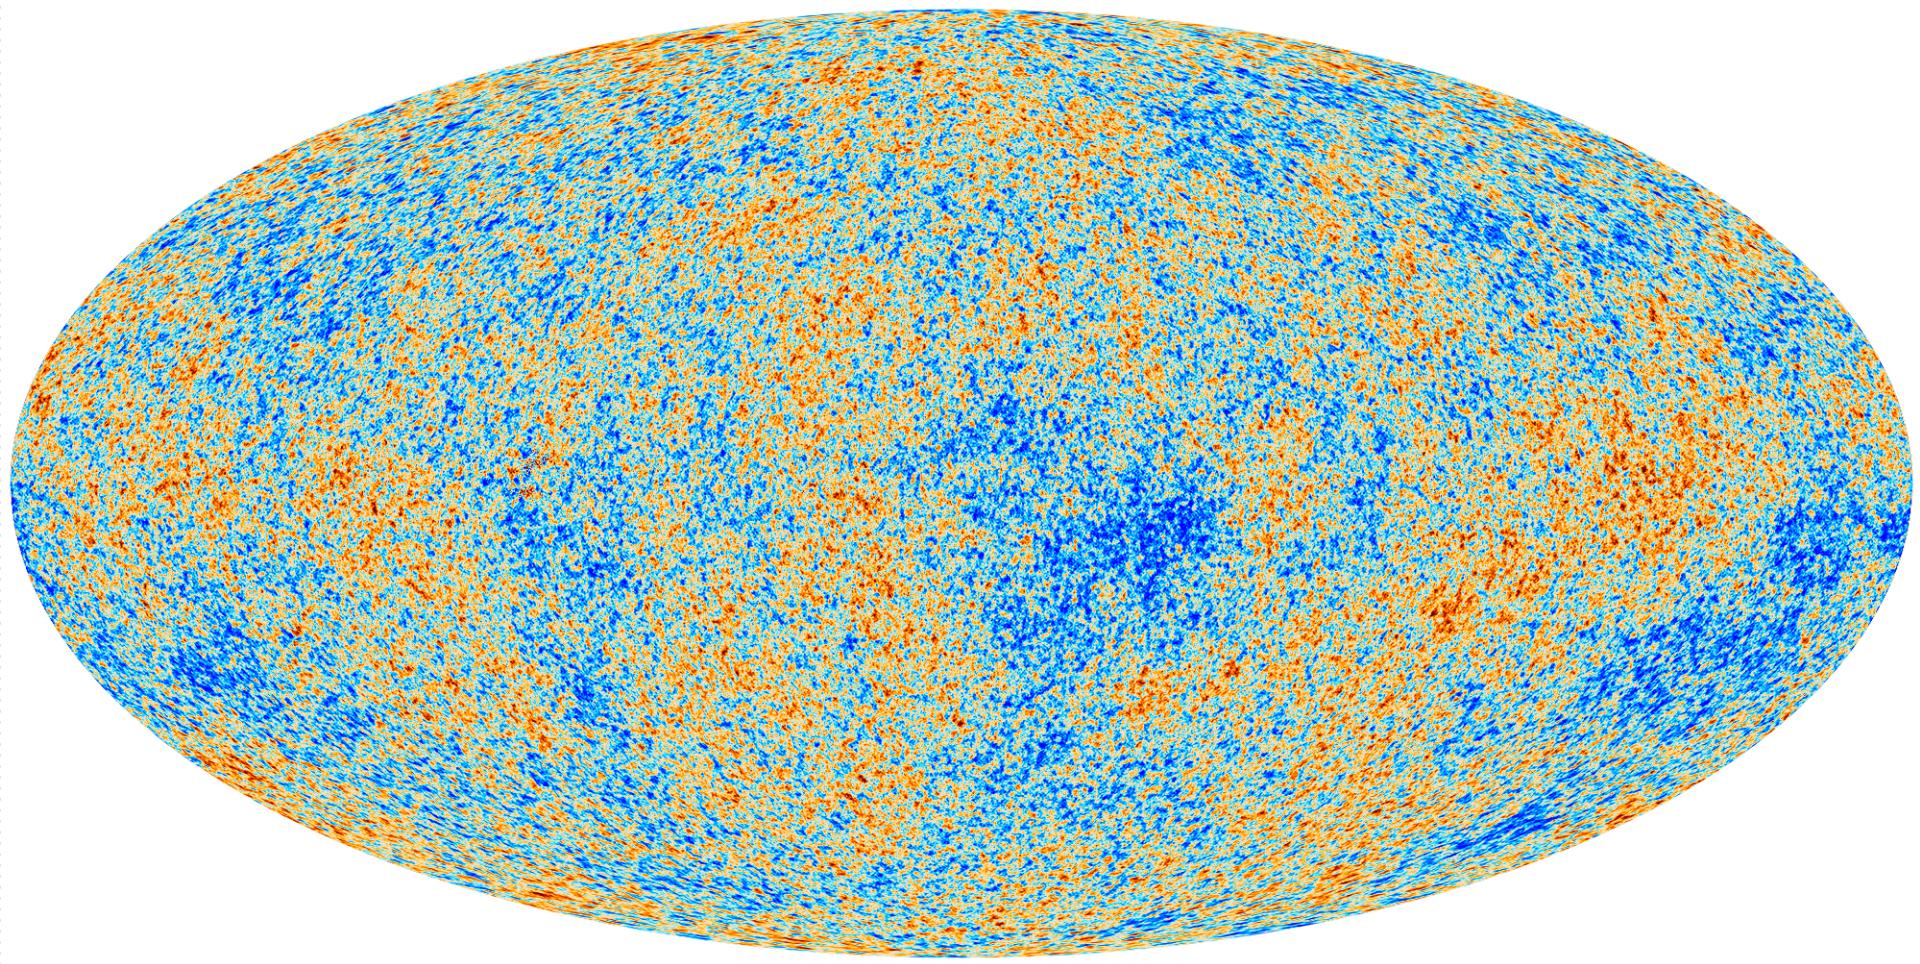

Outline

- Dark Matter – the present status
- Dark Matter indirect detection
- Fermi-LAT 130 GeV gamma-ray line
as a potential signal of DM
annihilations/decays
- Conclusions

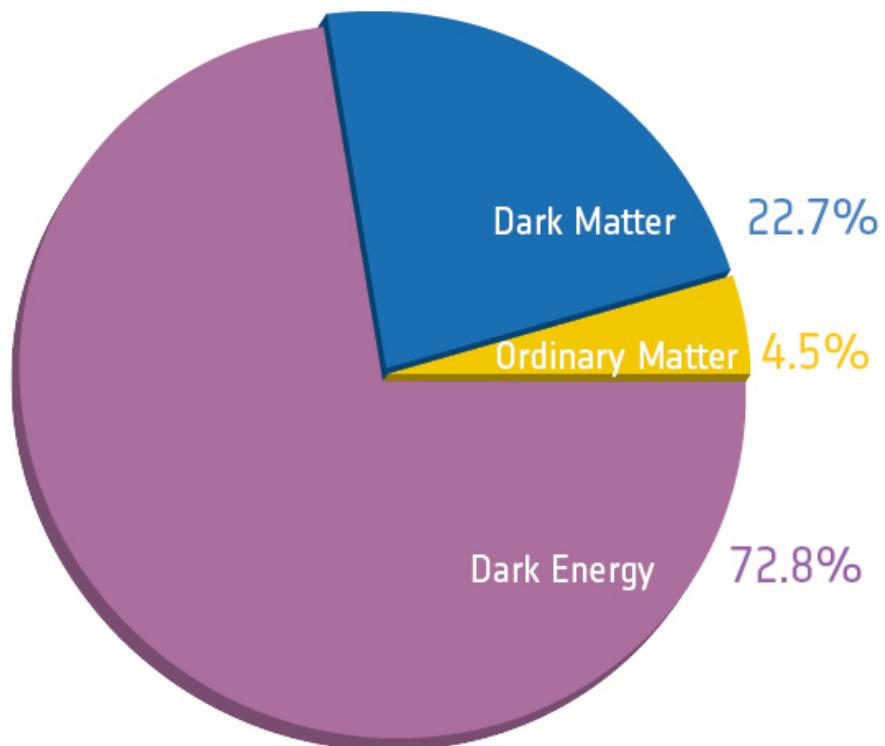

Where is physics beyond the SM?

- The discovery of Higgs proves the SM!
 - LHC: NP can be 20% perturbation around SM
 - Flavour, confinement?
- SM does not have a Cold DM candidate
- Look at the sky!

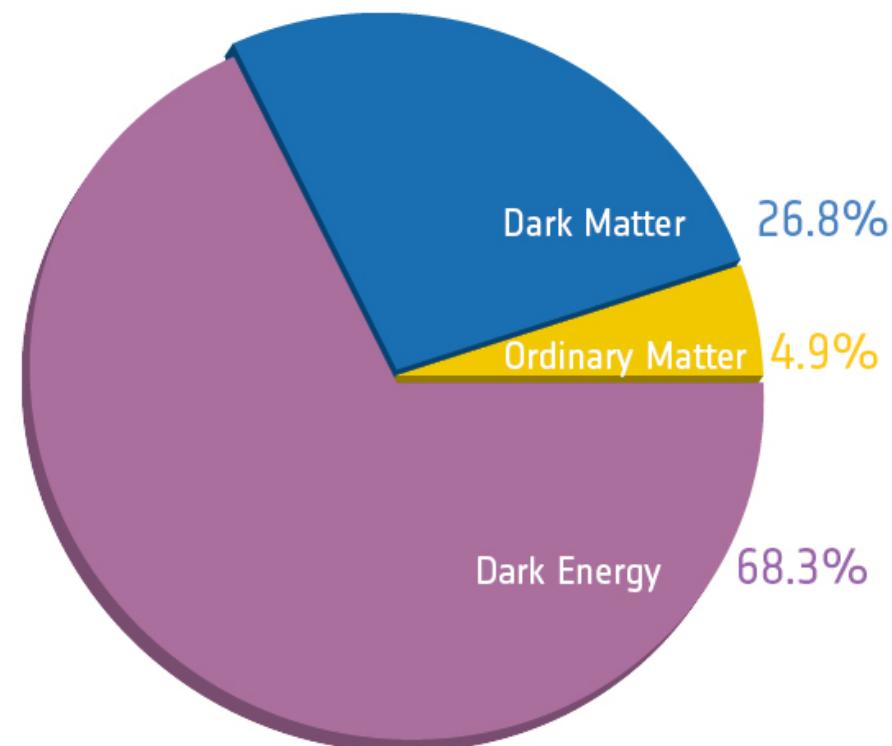

The global picture after Planck Mission (March 2013) - Λ CDM

Energy budget of the Universe

Before Planck

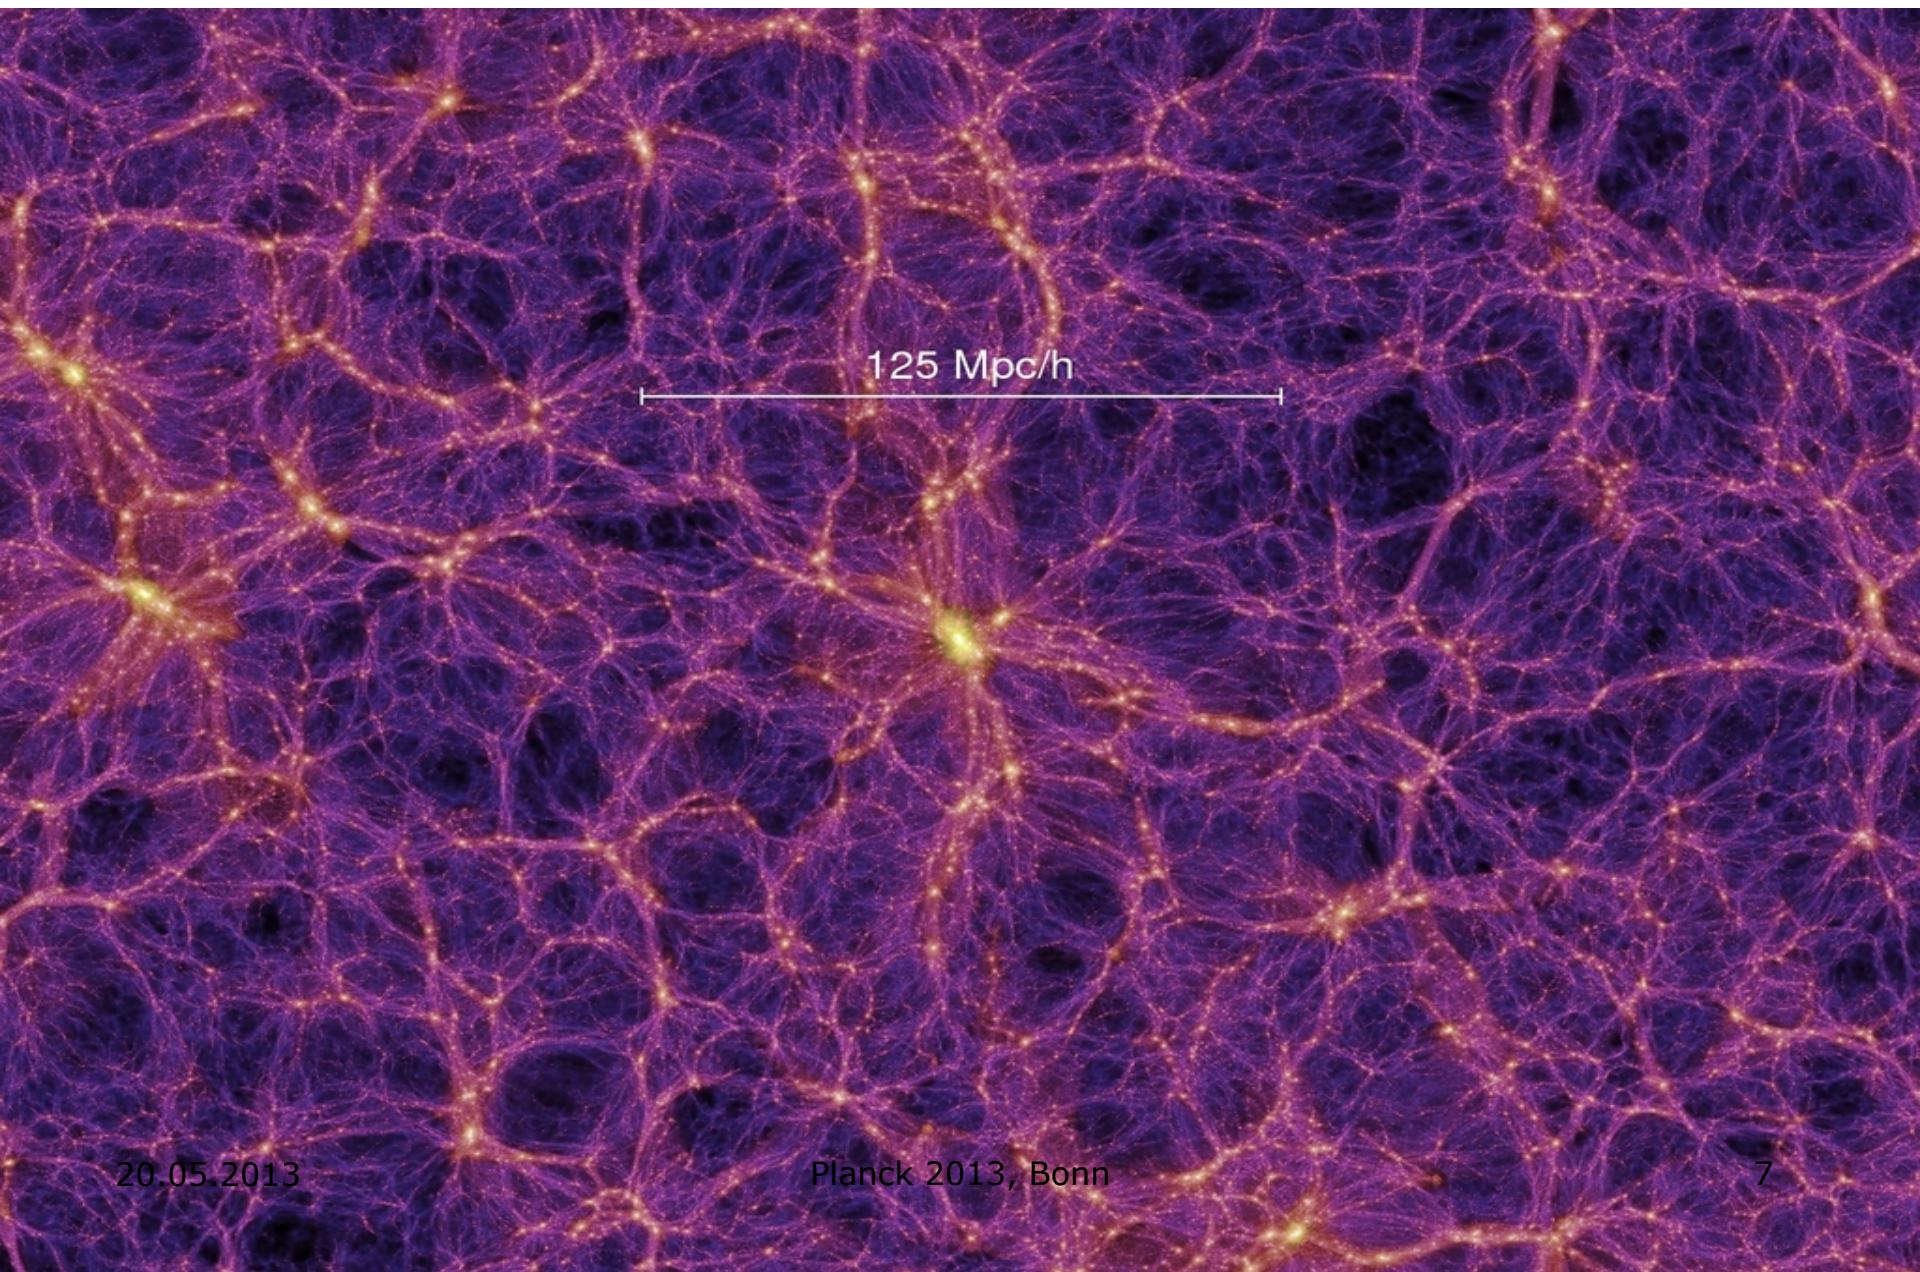

After Planck

What do we know about DM?

- DM does exist!
 - Evidence for it is all gravitational
 - Rotation curves of galaxies and clusters
 - Bullet clusters
 - Gravitational lensing
 - Formation of large scale structure
 - Baryon acoustic oscillations
 - All the evidences consistent with Λ CDM
-

Large scale structure of the DM

What is Dark Matter?

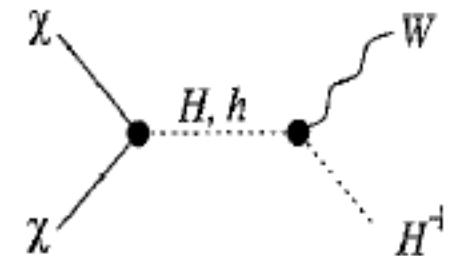

- No firm particle physics evidence so far
 - Theory: too many candidates
 - Massive neutrinos (warm DM)
 - Axions
 - WIMPs (neutralinos, gravitinos etc)
 - WIMPZillas
 - Proposed masses vary some 30-40 orders of magnitude
-

How is dark matter generated?

- DM is symmetric thermal relic

$\text{DM} + \text{DM} \rightarrow \text{SM} + \text{SM}$

- The WIMP miracle
- The annihilations should occur also today

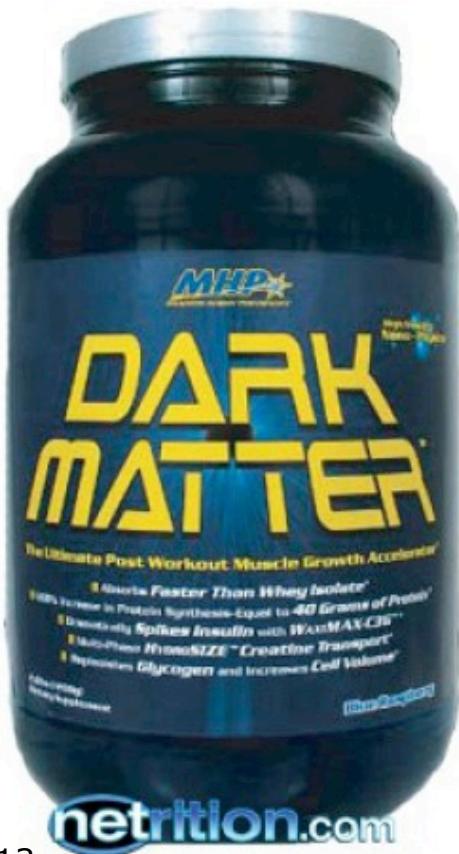

- DM is due to asymmetry

$X \rightarrow \text{SM} + \text{DM}$

- DM abundance related to baryon asymmetry of the Universe
- $\Omega_{\text{DM}} = 5 \Omega_b, m_p = 1 \text{ GeV} \rightarrow M_{\text{DM}} = 5 \text{ GeV}$

DM available in internet for the reduced price!

How to detect Dark Matter of the Universe?

The main ways to detect WIMPs

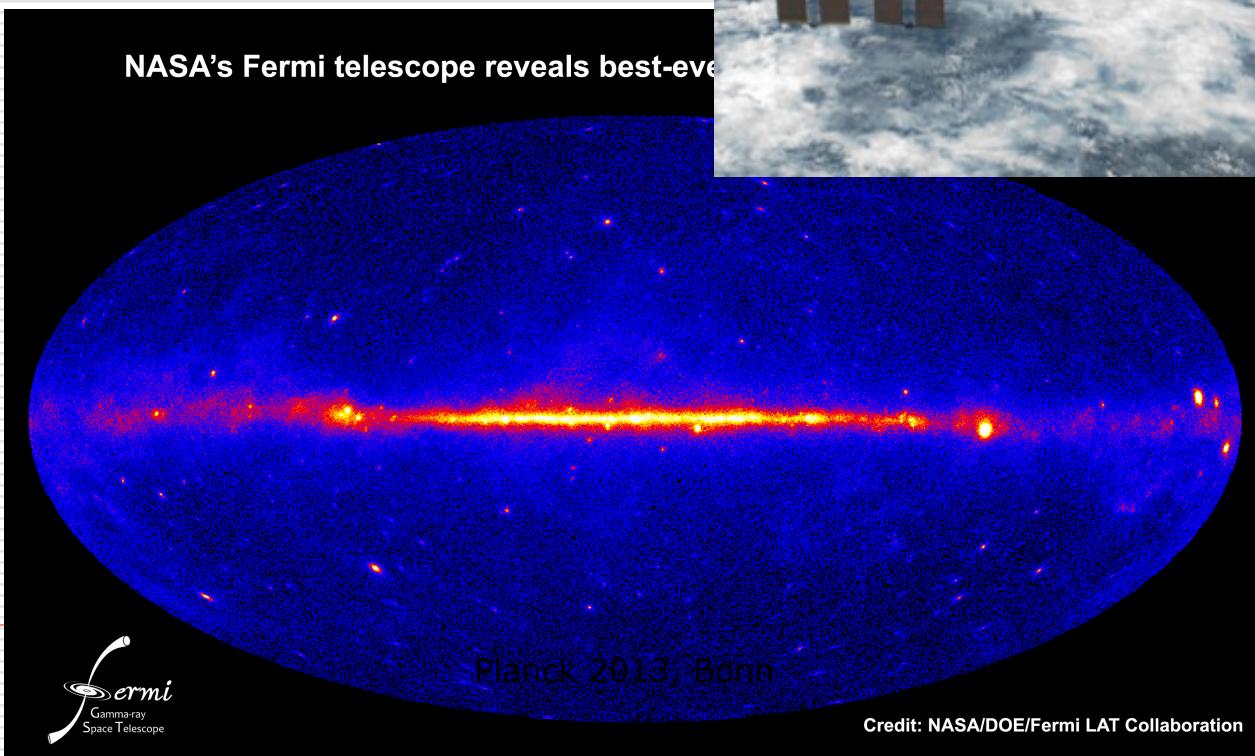

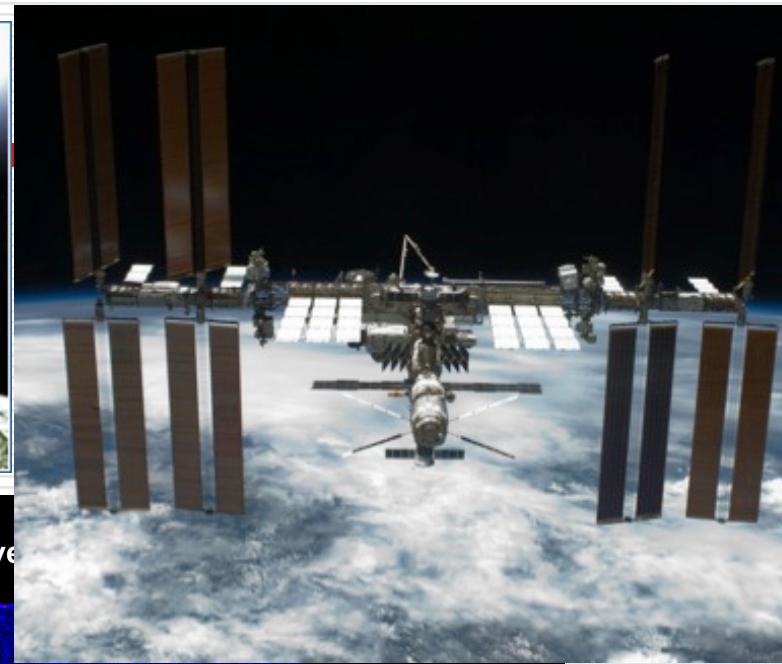

□ Direct detection

- Search for DM recoils on nuclei in very sensitive underground experiments
- XENON, CDMS, DAMA, COGENT, LUX etc
- Search for DM particles at the LHC experiments

□ Indirect detection

- Search for cosmological signals of DM annihilations/decays today
- PAMELA, FERMI, AMS02, ATIC, HESS

Astroparticle physics – new HEP

DM indirect detection

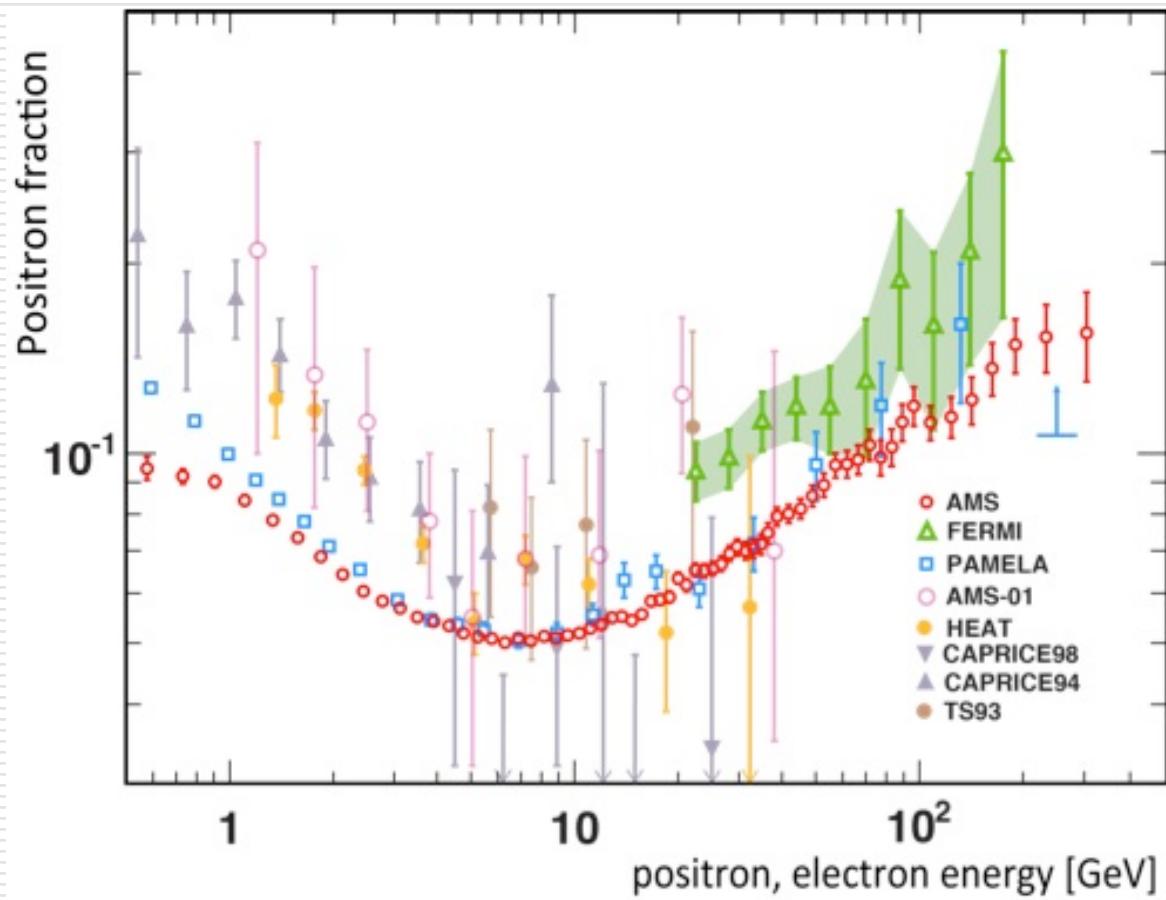

- Indirect search – look for DM annihilation/decay products today
 - Detect anti-particles in cosmic rays
 - Loose both energy and direction
 - **Photons** are easily detectable
 - Show the direction of the source
 - May exhibit spectral features
 - Look at dense DM objects like Galactic Center, galaxy clusters, LSS filaments
-

Fermi-LAT gamma-ray data is publicly available

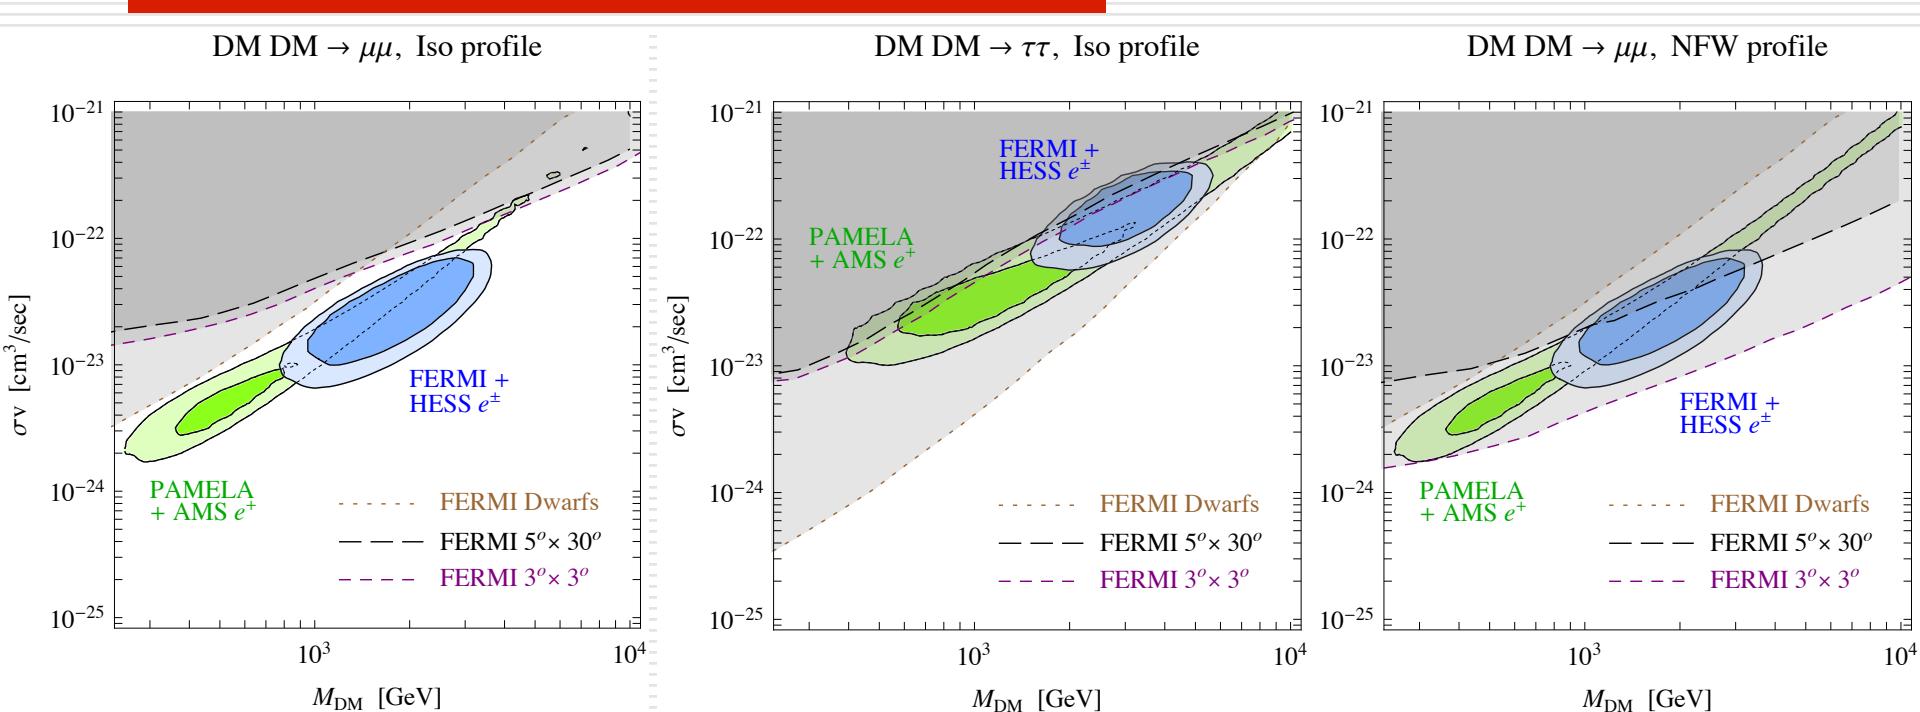

- Detects cosmological objects
- Can check the PAMELA, Fermi, AMS positron excess with associated **secondary** photons
- Can look for new excesses and spectral features in **primary** gamma-rays

AMS02 – confirms PAMELA, Fermi

Global status of DM annihilations after AMS02 – strongly constrained

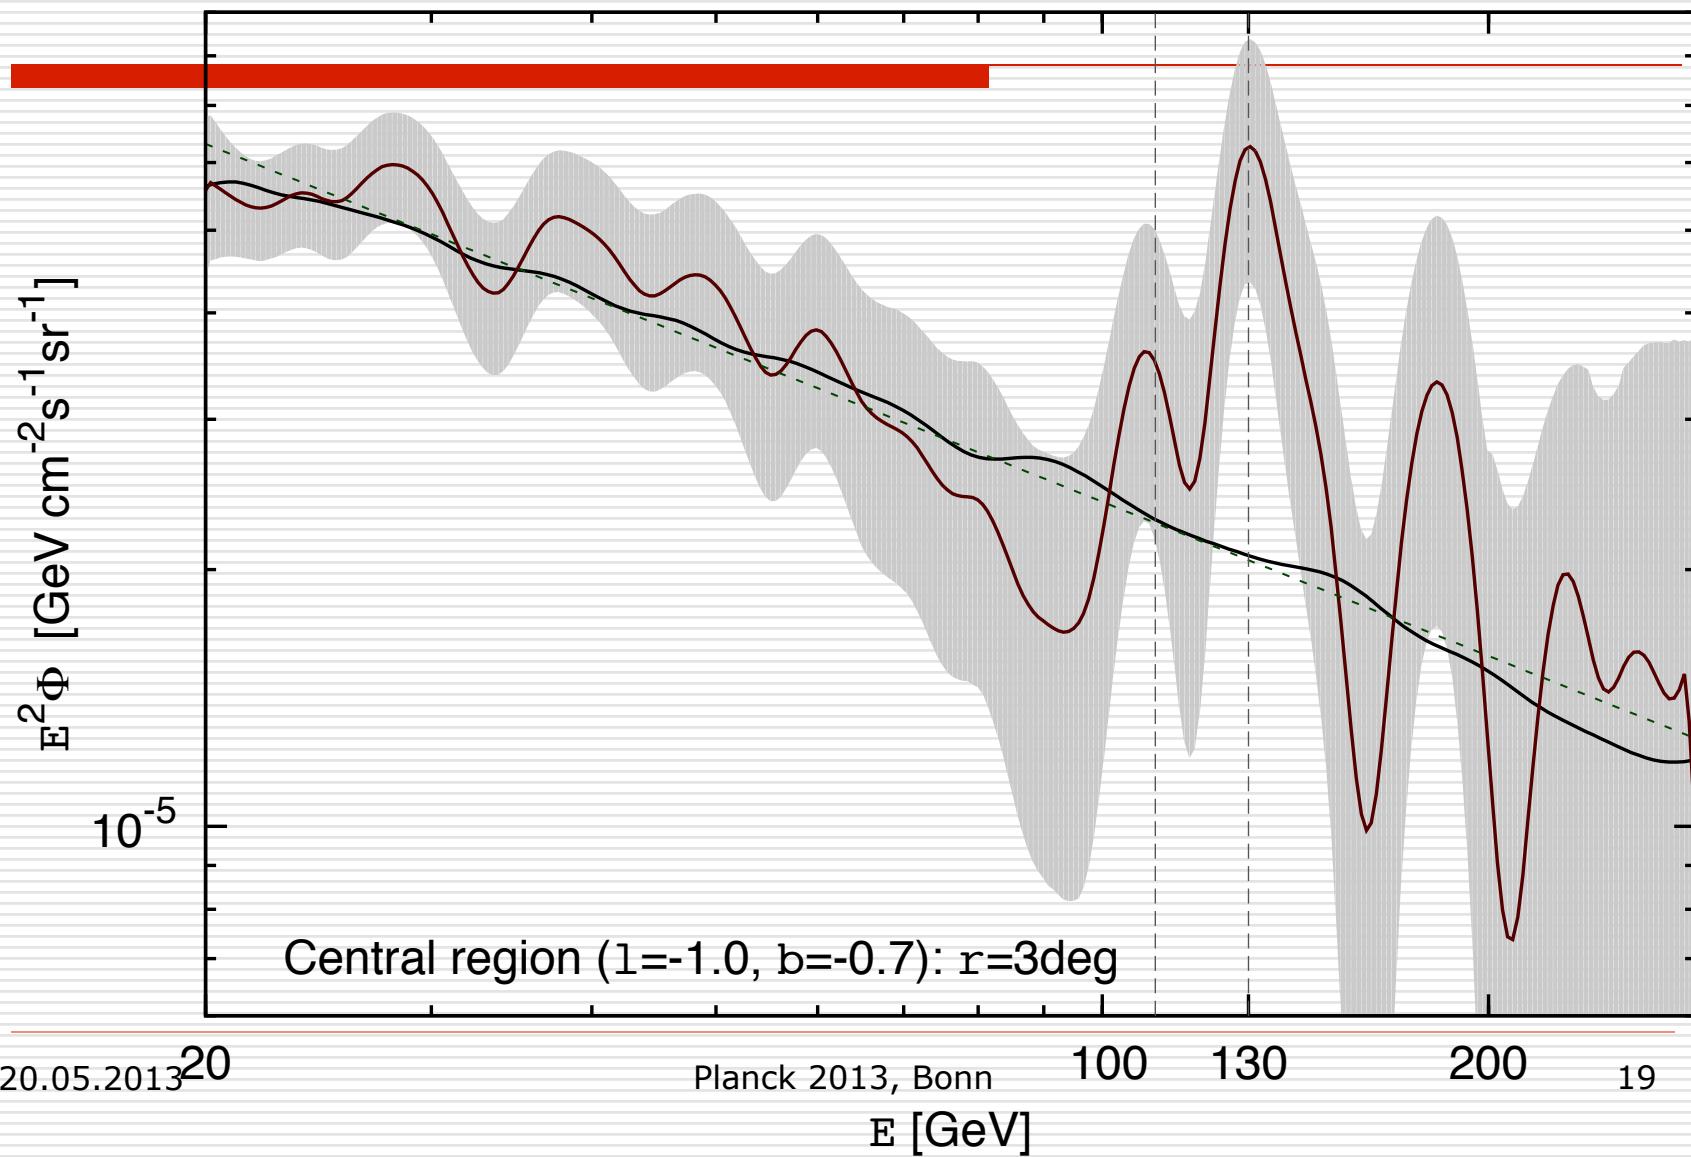

- No aniprotons – requires **leptophilia**
- Cross section must be **1000x enhanced**
- New non-standard approach/view on the problem needed

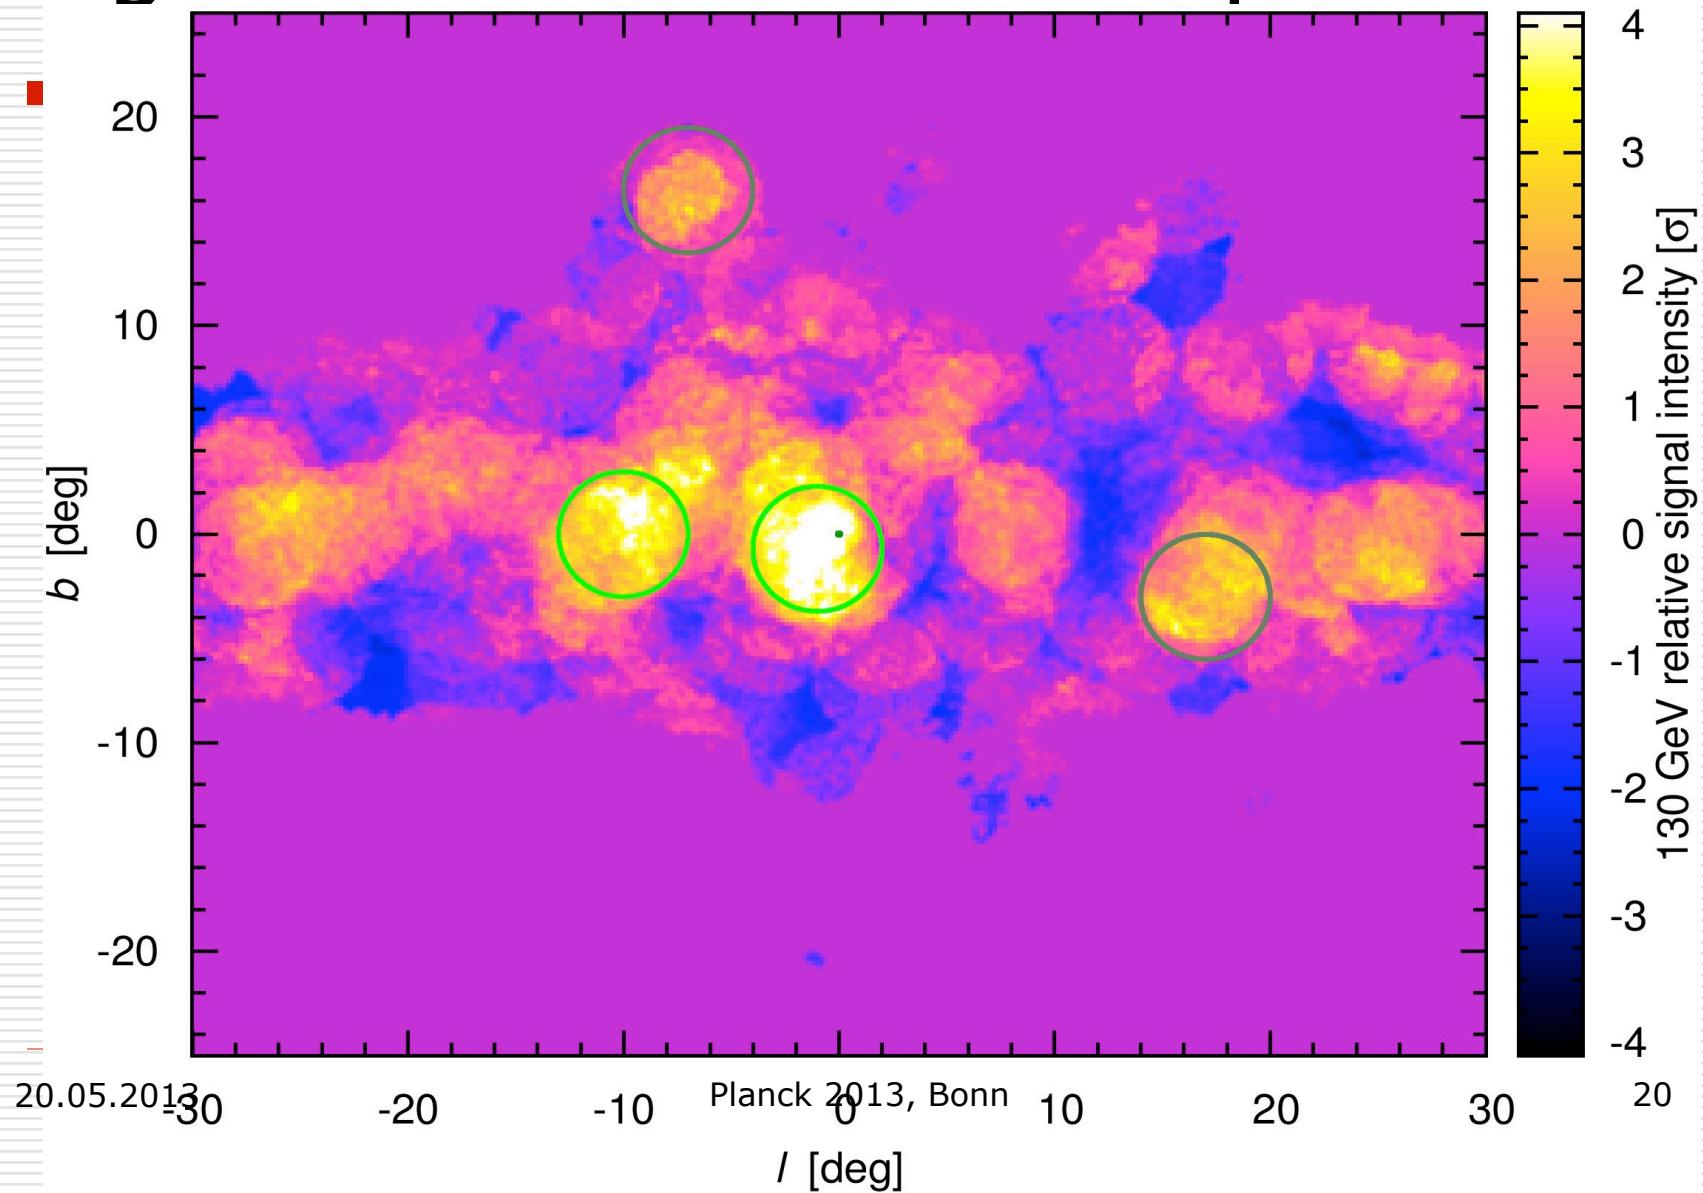

A surprise – 130 GeV gamma-ray line in public Fermi data from GC

- The line was discovered by Bringmann, Huang, Ibarra, Vogl, and Weniger
 - Shortly confirmed by Tallinn (Hektor, Raidal, Tempel) and Harvard (Finkbeiner, Su) groups
 - Questions of its origin:
 - Is it associated with known cosmological mechanism like creation of Fermi bubbles?
 - If it signals DM annihilations, what is the particle physics behind it?
-

Double peak, significance varies between $4.5\text{-}6.5\sigma$

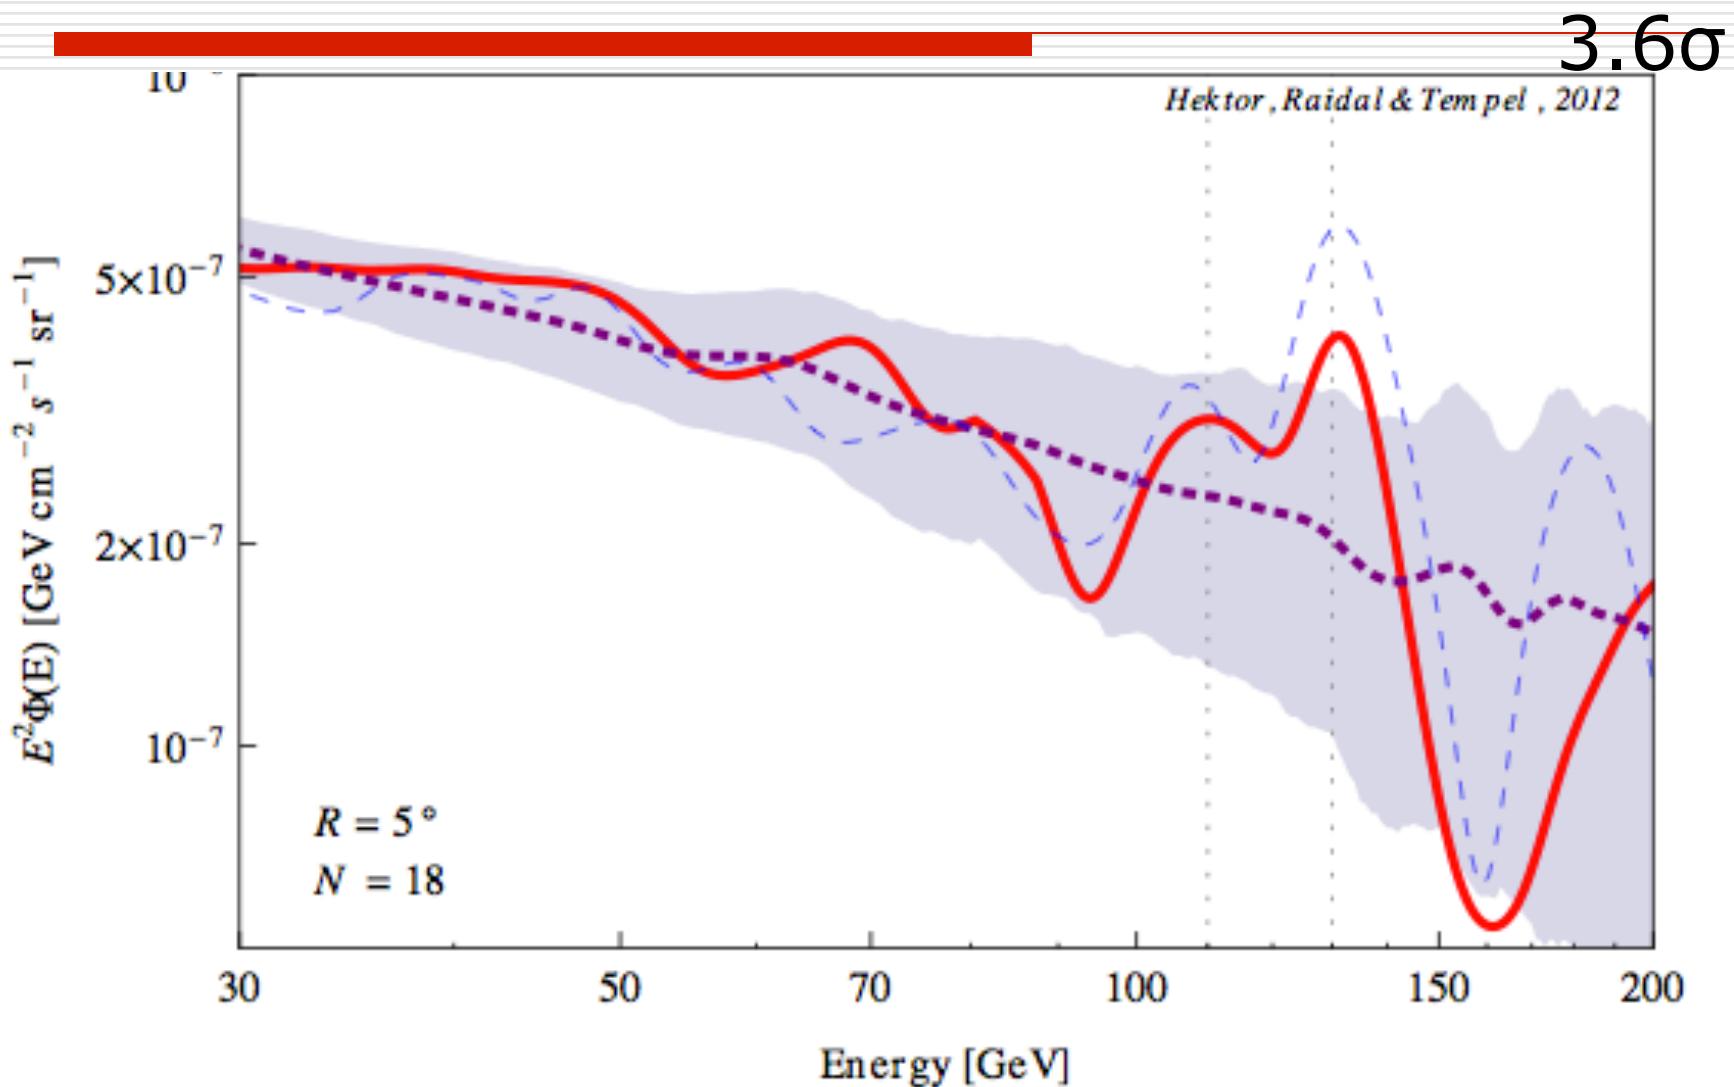

Signal originates from the GC! The brightest centre little displaced!

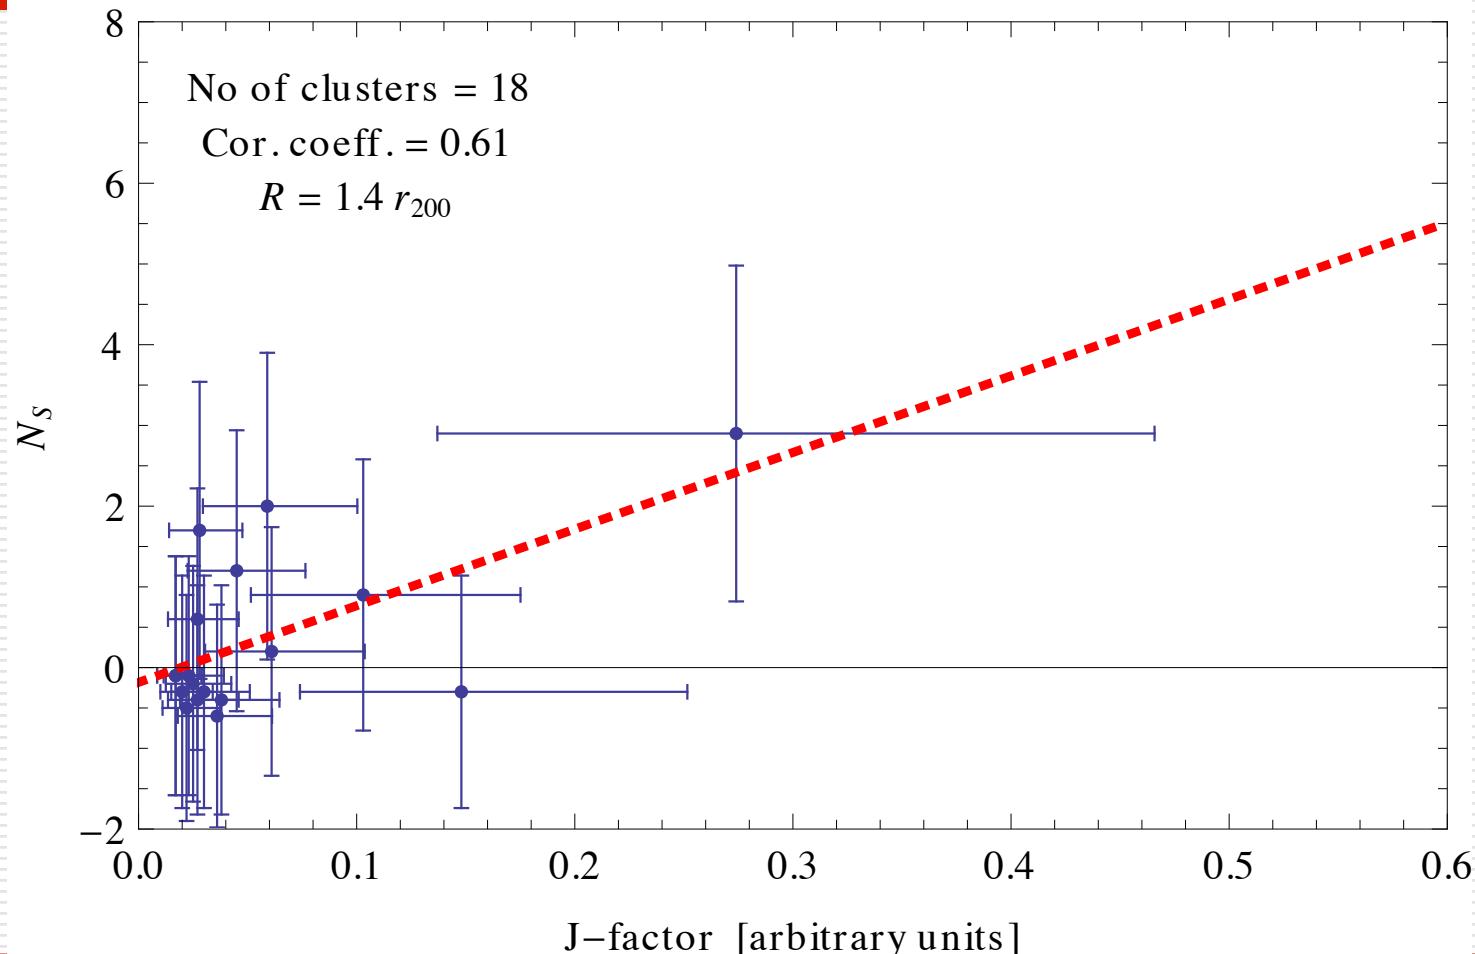

Look for signal from other DM rich objects – the galaxy clusters

- Galaxy clusters should be ideal for looking for DM annihilations due to the **boost of the signal induced by the DM substructure**
- We studied the signal from the brightest nearby galaxy clusters

Galactic centre vs. galaxy clusters

Number of signal photons vs. brightness of the galaxy cluster

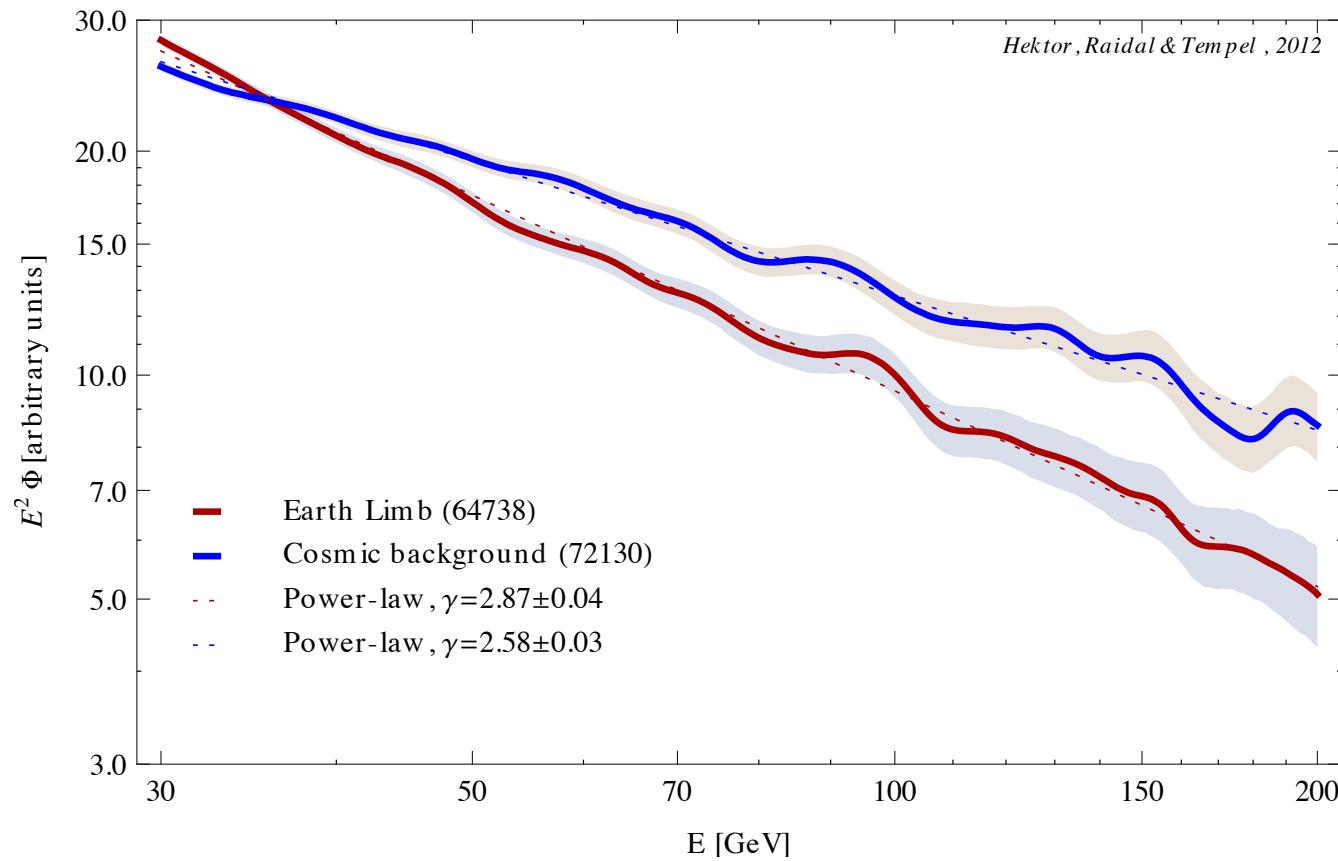

Particle physics interpretation

- ❑ DM vs. astrophysics? – **the DM!**
 - ❑ The double peak refers to $\gamma\gamma$, γZ , γH final states
- ❑ DM annihilations preferred over decays
 - ❑ Morphology of the GC signal ρ^2 (Weniger)
 - ❑ Boost factor 10^{2-3} from the galaxy clusters
- ❑ Annihilation xs **0.1 σv , too big for a loop**
 - ❑ Internal bremsstrahlung, $DM+DM \rightarrow SM+SM+\gamma$
 - ❑ Large anomalies (DM “almost” charged)
 - ❑ **Natural** annihilation into intermediate states X, $DM+DM \rightarrow X X$, followed by $X \rightarrow \gamma\gamma, \gamma Z$ with 10%

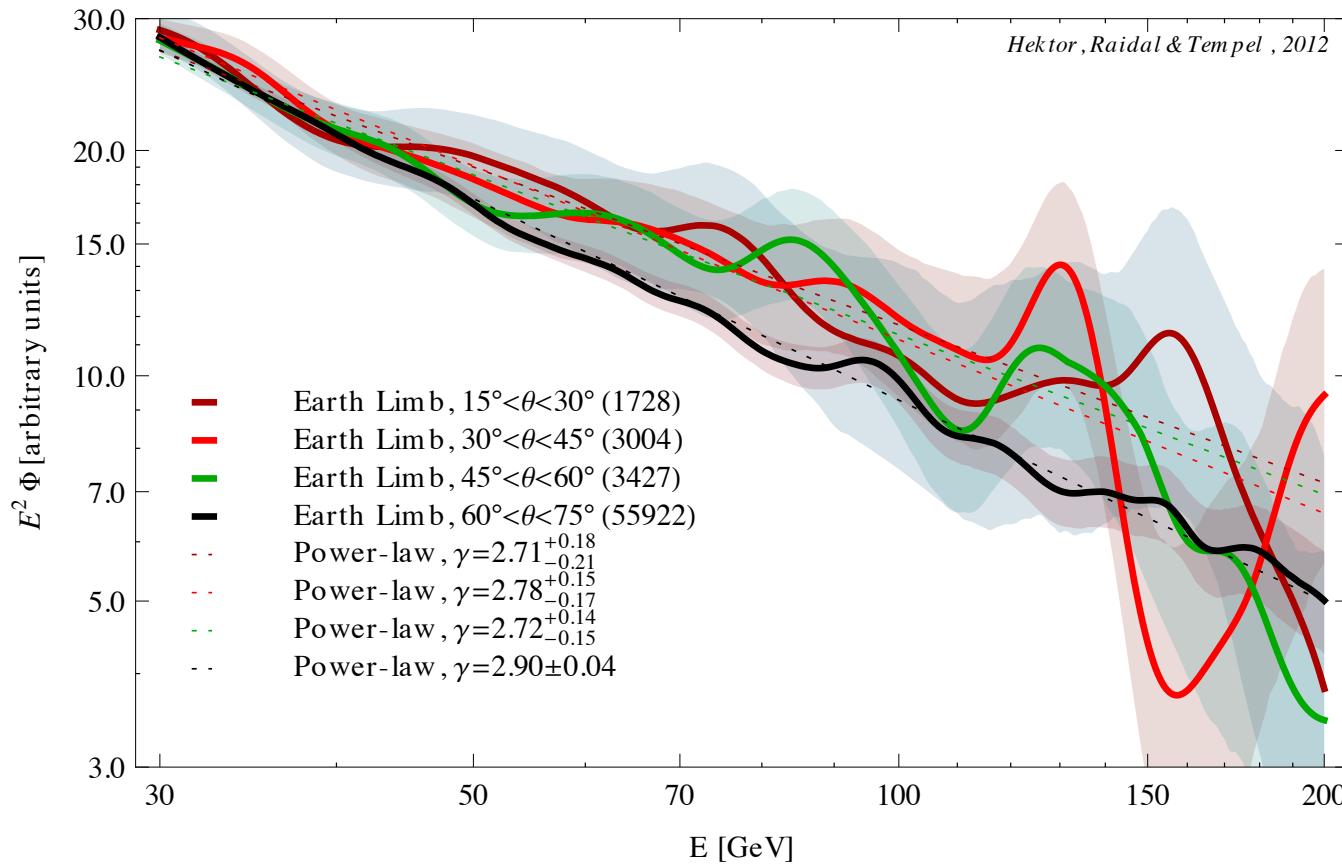

Fermi Symposium 2012 – an important milestone

- Fermi-LAT Collaboration finally confirmed the excess but:
 - With smaller statistical significance
 - Using re-processed data (not publicly available)
- No official claim by the Collaboration but
 - The excess shifts to higher energy, 135 GeV
 - Similar excess in the Earth Limb data
- If Earth Limb data is taken as region of interest for comparison, the GC excess reduces

Cosmic diffuse background vs. Earth limb – all available data

Subset of Earth limb data shows an excess without the double peak

Is it fake detector effect or real signal of DM?

- We, theorists, can work only with publicly available data
- Check the **consistency** of the data for
 - Different regions of interest
 - For different detector parameters such as the incidence angle θ
- No obvious effects are seen in data
 - The excess seen only in special regions
 - We see no anomalous dependences on θ

Detector effects continued ...

- We believe there are good reasons behind the pessimism of the Fermi-LAT Collaboration
- Those are not obvious when working with the publicly available data
- Wait for the recalibrated Fermi-LAT data
- The 130 GeV excess should be cross-checked by AMS02 and new experiments

Present status of the 130 GeV gamma-ray excess

- Double peak signal is seen from GC and from galaxy clusters (5σ and 3.5σ)
 - The double peak, morphology of GC signal, boost from galaxy clusters favor DM annihilations as the interpretation
 - If confirmed, DM properties must be strange since DM is expected be “dark”
 - **Fermi Collaboration has confirmed the excess but not the interpretation**
-
