

The E-906/SeaQuest Experiment

Monday 25 August 2014 15:40 (20 minutes)

The E-906/SeaQuest experiment at Fermilab continues a series of Drell-Yan measurements to explore the antiquark structure of the nucleon and nuclei. To extend existing measurements to larger values of Bjorken- x , a 120 GeV proton beam extracted from Fermilab's main injector is used, resulting in a factor of 50 more luminosity than previous experiments and enabling access to values of x up to 0.9. An overview will be presented of the key physics goals of the E-906/SeaQuest collaboration. These include investigation of the dramatic $d\bar{u}/u\bar{d}$ flavor asymmetry in the nucleon sea and its behavior at high x ; study of the EMC effect in Drell-Yan scattering and the unexpected absence of any antiquark excess in existing data; and measurements of the angular dependence of the Drell-Yan process, sensitive to spin-orbit correlations within the nucleon. Updates to the SeaQuest experiment with polarized beam (E-1027) and target (E-1039) will allow to study the spin-orbit correlations in the analysis of single-spin asymmetries providing complimentary information to the existing SIDIS data. The talk will conclude with a status report on the ongoing data taking and data analysis of this new experiment.

Primary author: Dr DIEFENTHALER, Markus (University of Illinois at Urbana-Champaign)

Presenter: Dr DIEFENTHALER, Markus (University of Illinois at Urbana-Champaign)

Session Classification: Quarks and gluons in hadrons, the hadron spectrum

Track Classification: 2) Quarks and gluons in hadrons, the hadron spectrum
