

# **MVA Techniques II: Advanced Methods**

### S. Gleyzer<sup>1</sup>, H. Prosper<sup>2</sup>, C. Rosemann<sup>1</sup>

<sup>1</sup>DESY, <sup>2</sup>Florida State University

DESY Statistics School 2014 April 3, 2014

### Part II

- Focus on advanced multivariate methods
  - Methods in Theory
    - Overview
  - Methods in Practice
    - Classification Tutorials
      - Simple gaussians, H→ ZZ→ 41 example
    - Regression Tutorials
      - Calorimetry exercise, function estimation with Bayesian Neural Networks

### Resources

### Literature

G. James, et al. "Introduction to Statistical Learning" Springer 2013

C.M. Bishop "Pattern Recognition and Machine Learning" Springer 2006

J. R. Quinlan "C4.5: Programs for Machine Learning" Morgan Kaufmann 1992

CLUS <a href="http://dtai.cs.kuleuven.be/clus/">http://dtai.cs.kuleuven.be/clus/</a>

# **Applications**

# Many in HEP Some typical use cases

- Classification
  - Particle identification (ID)
    - Is this a **pear** (photon/electron) or an **apple** (jet)?
  - Searches for new physics
    - Various MVA methods used by past and current physics analyses to find new physics or set limits on theoretical models
      - Does this look like SUSY or background event?

### Regression

- Calorimetry
  - Energy deposited by particles in non-compensating multi-layered calorimeter better measured by a function of individual energy deposits, cluster shapes obtained with MVA

# **Classification Methods**

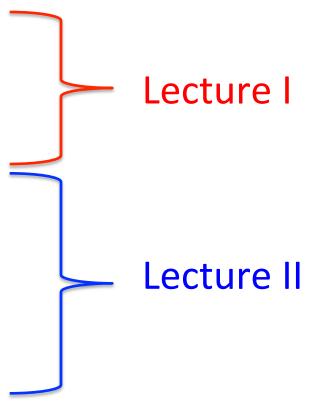

### **Available Methods**

Again a *short* list of multivariate (MVA) methods that can be used for classification:

- Random Grid Search
- Fisher Discriminant
- Quadratic Discriminant
- Naïve Bayes (Likelihood)
- Kernel Density Estimation
- Binary Decision Trees
- Neural Networks
- Bayesian Neural Networks
- Support Vector Machines
- Random Forests
- Genetic Algorithms
- Predictive Clustering

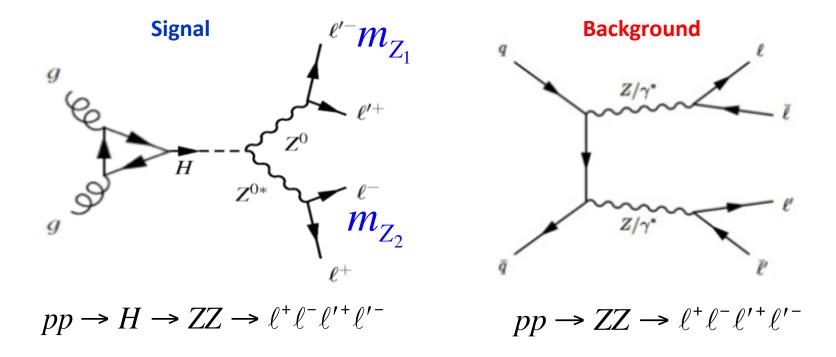

# **Illustrative Example**

# H to ZZ to 4 Leptons

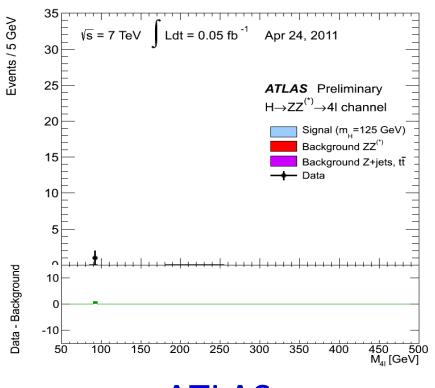

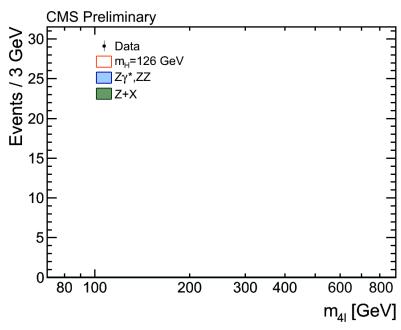

We'll (re)use this example to illustrate a few of the methods.

# H to ZZ to 4 Leptons

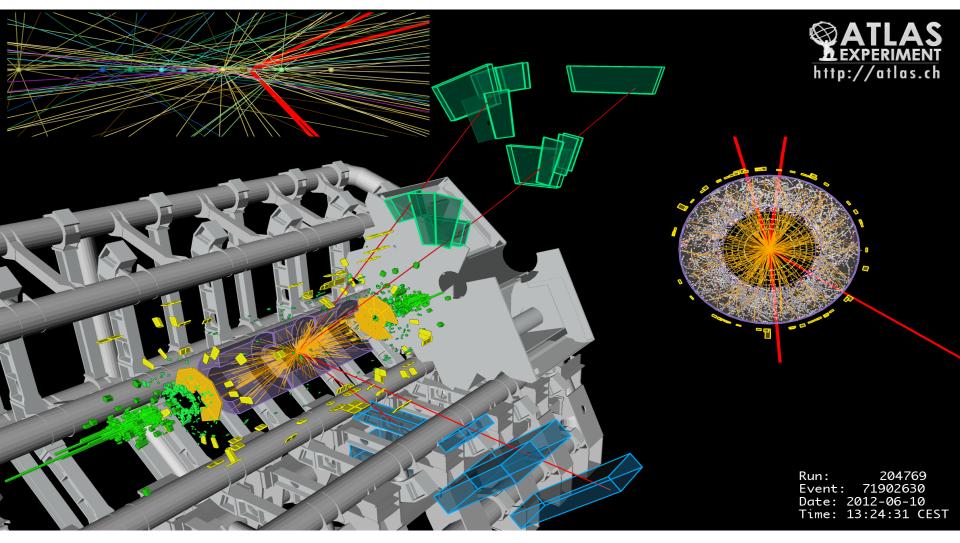

**ATLAS** 

**CMS** 

# **4-Lepton Event ATLAS**

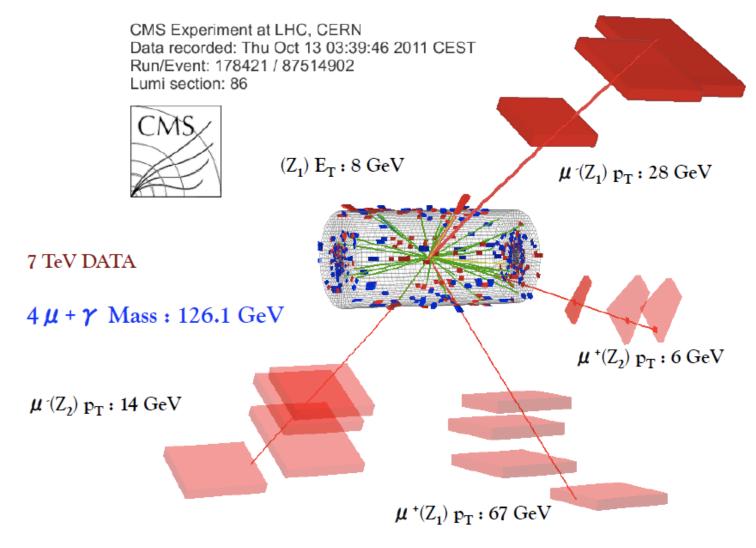

# 4-Lepton Event CMS

### **Feature Selection**

### **Feature Selection**

### **Picking variables:**

- Usually pick variables (features) that show standalone discrimination power
- Try to cover all degrees of freedom
  - don't worry if you end up with a few extra variables, they can be winnowed afterwards

Important! how well the variables work together in the classifier

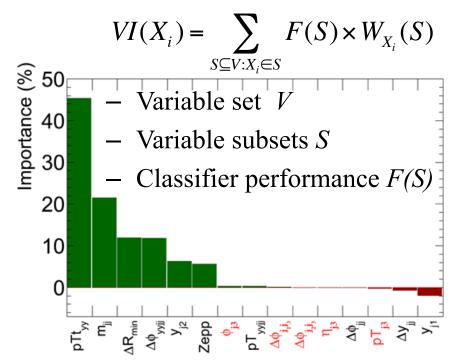

### **Feature Selection**

# Paradigm: tool for variable selection in classification context

Variable importance

proportional to classifier performance in which variable participates

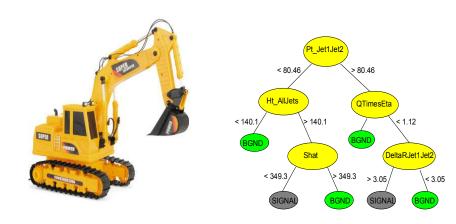

$$W_{X_i}(S) = 1 - \frac{F(S - \{X_i\})}{F(S)}$$

Amount of classifier loss (or gain) if variable  $X_i$  is removed

# **Building Classifiers**

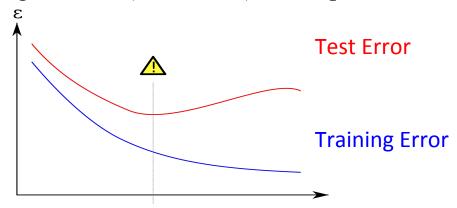

# **Training**

In supervised (as opposed to unsupervised or semisupervised) learning scenario, data are labeled at the training stage

- Split data into at least two sets
  - Keep training and test (evaluation) sets separated

- Monitor training/test error rates
  - Watch out for overtraining

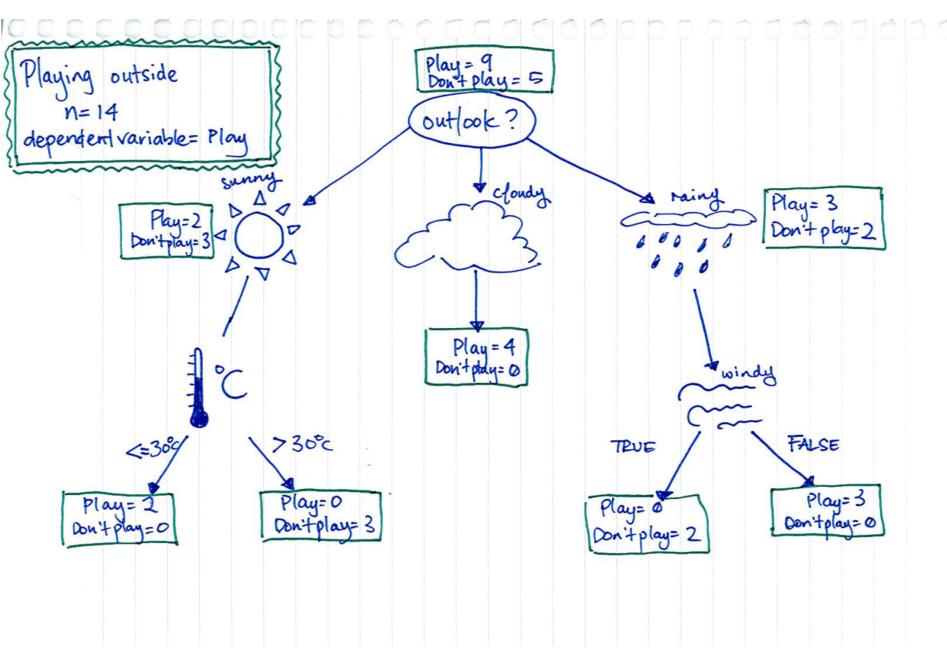

# **Binary Decision Trees**

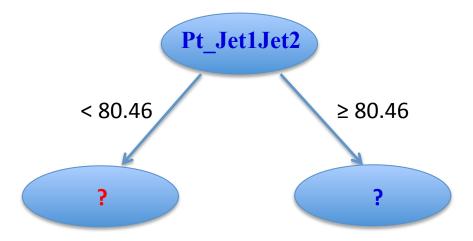

# **Binary Decision Trees**

### **Building a tree:**

- Scan along each variable and propose a DECISION
  - A cut on value that maximizes class separation (binary branching)

# **Binary Decision Trees**

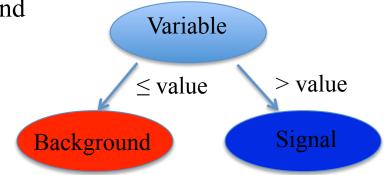

### **Building a tree:**

- Choose decision that leads to greatest separation among classes signal/background
  - Based on the information gained from split
    - Build regions of increasing purity
    - Stop when no further improvement from additional branching

$$\frac{N_{signal}}{N_{signal} + N_{background}}$$

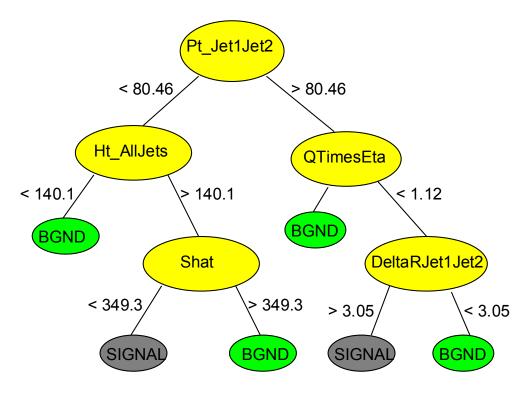

# Representation

### 2-D Example

# X<sub>2</sub>

### **Typical N-D Tree**

# **Pruning**

Decision trees can become large and complex and risk over-fitting the data

Pruning: remove parts of the tree that are less powerful or possibly noisy

start from the leaves and work back up

Pruned trees smaller in size, easier to interpret

# **Over-Training**

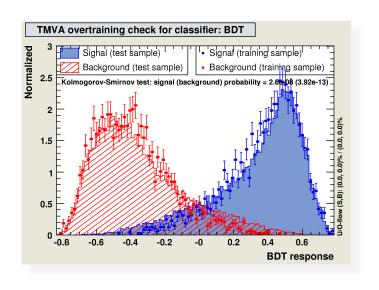

Over-training or over-fitting sometimes occurs when too many parameters for data size

### Diagnose with

- divergent Training/Testing error slopes
- K-S test

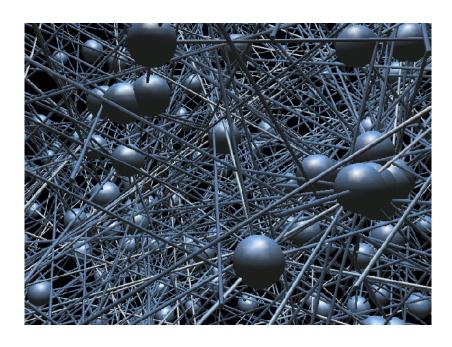

### Treat with

- Prune decision trees
- Winnow: reduce number of parameters

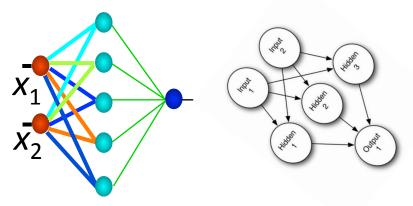

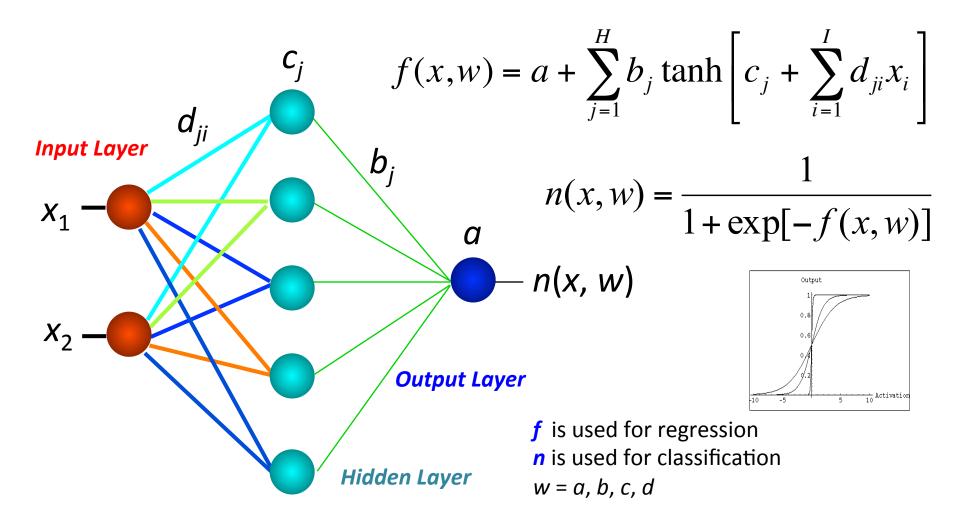

# **Neural Networks (NN)**

# **Graphical Representation**

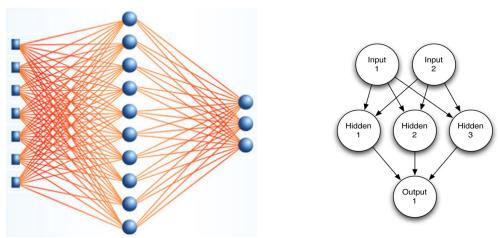

# **Network Weights**

# Compute optimal network weights with derivatives dE/dw

Calculate gradients of errors for adjustable weights

Inputs go forward in feed-forward neural networks Errors go backward! **Back-propagation** 

### **Neural Networks**

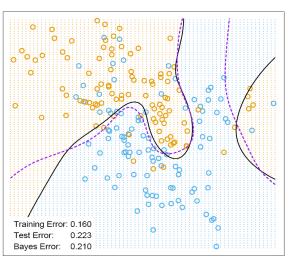

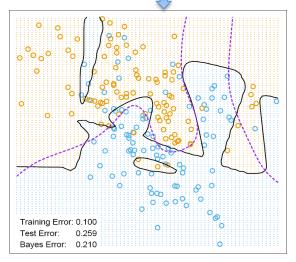

### Can approximate any continuous function

Complexity determined by number of hidden layers and hidden nodes/layer

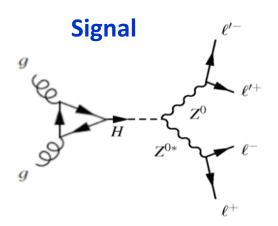

### Many types of neural networks!

Watch out for overtraining

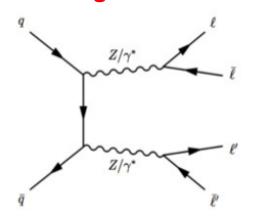

# H to ZZ to 4Leptons

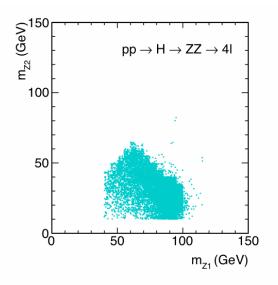

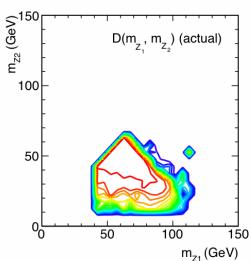

$$pp \rightarrow H \rightarrow ZZ \rightarrow \ell^+ \ell^- \ell'^+ \ell'^-$$

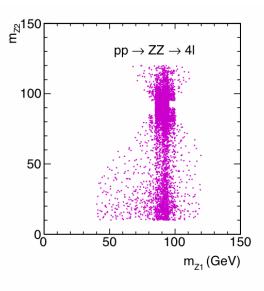

### **Background**

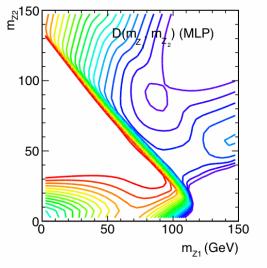

$$pp \rightarrow ZZ \rightarrow \ell^+\ell^-\ell'^+\ell'^-$$

### **Classifier Performance**

### **Classifier Performance**

Receiver Operating Characteristic (ROC)

curve

### **Commonly used metric**

Shows the relationship between correctly classified positive cases (sensitivity) and incorrectly classified negative cases (1-effectivity)

# Perfect Classifier | Supplies | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8 | 10.8

### Classifier Performance

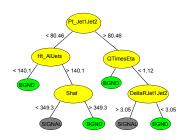

### Receiver Operating Characteristic (ROC)

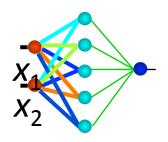

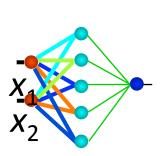

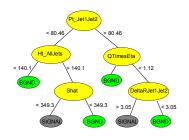

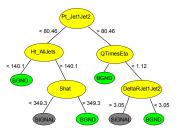

### **Ensemble Methods**

### **Ensemble Methods**

Suppose you have a collection of discriminants  $f(x, w_k)$ , which, individually, perform only marginally better than random guessing.

$$f(x) = a_0 + \sum_{k=1}^{K} a_k f(x, w_k)$$

From such discriminants, weak learners, it is possible to build highly effective ones by averaging over them:

Jerome Friedman & Bogdan Popescu (2008)

### **Ensemble Methods**

Usually used with decision trees but they are more general. Most popular methods are:

### **Bagging**

• Each tree trained on a **bootstrap sample** drawn from training set

### **Random Forest**

- Bagging with randomized trees
  - Random subsets of features used at each split

### **Boosting**

• Each tree trained on a **different weighting** of full training set

# **Adaptive Boosting**

# **Adaptive Boosting**

#### Train in stages

- Adaptive weights
  - ADABoost: Freund & Schapire 1997
- Misclassified events get a larger weight going into the next training stage
  - Classify with a majority vote from all trees
- Works very well to improve classification power of "greedy" decision trees
  - can be used with other classifiers

# **Adaptive Boosting**

#### Repeat K times:

- 1. Create a decision tree f(x, w)
- 2. Compute its error rate  $\varepsilon$  on the *weighted* training set
- 3. Compute  $\alpha = \ln (1 \varepsilon) / \varepsilon$
- 4. Modify training set: *increase weight* of *incorrectly classified examples* relative to the weights of those that are correctly classified

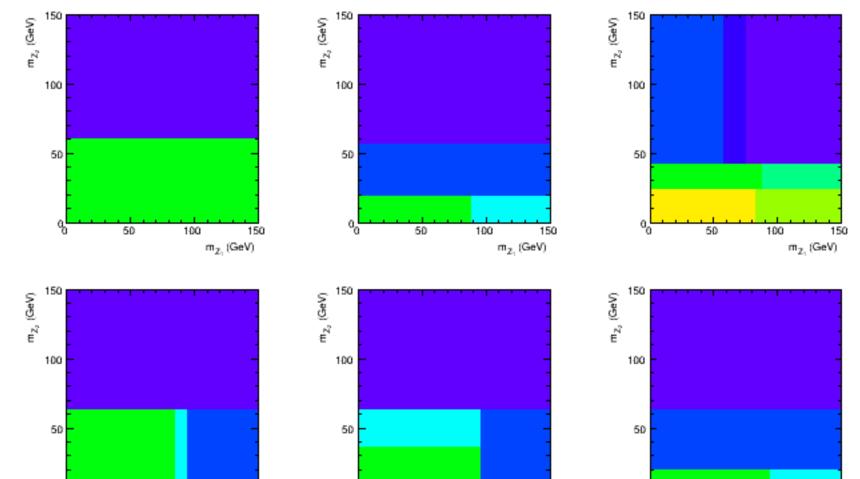

Then compute weighted average  $f(x) = \sum \alpha_k f(x, w_k)$ 

Y. Freund and R.E. Schapire. Journal of Computer and Sys. Sci. **55** (1), 119 (1997)

### H to ZZ to 4Leptons

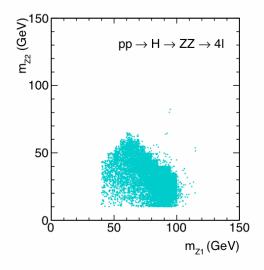

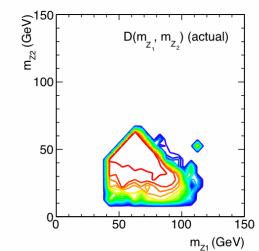

$$pp \to H \to ZZ \to \ell^+ \ell^- \ell'^+ \ell'^-$$

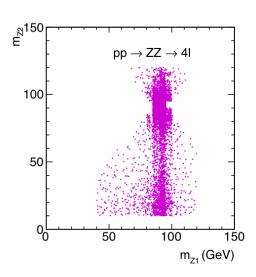

#### **Background**

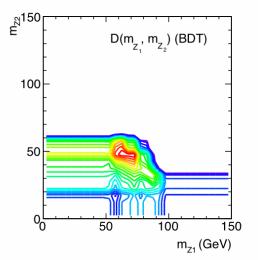

200 trees with a minimum of 100 counts per bin (leaf)

$$pp \rightarrow ZZ \rightarrow \ell^+\ell^-\ell'^+\ell'^-$$

#### **Function Estimation**

#### **Function Estimation**

by Gauss (1805)

Approximate trajectory of a comet from observations

Approach: minimize difference between measurement and predictions in a systematic fashion

#### **Function estimation**

- Think of decision trees as multidimensional histograms
  - Bins are recursively constructed
  - Each associated to the value of f(x) to be approximated
- To go from classification to regression change the evaluation criteria used in the learning algorithm
  - from maximum separation gain to minimal variance from resulting subspace cuts

# Regression Example

Improve calorimeter resolution by applying regression

Inputs: electromagnetic shower information, other calorimetric variables

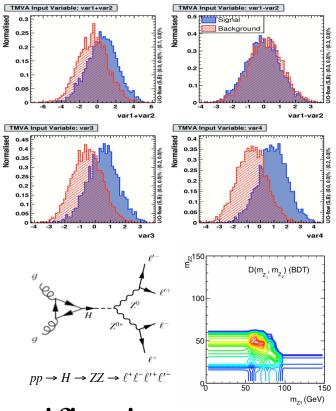

Target Output: calorimeter energy

#### **Exercises**

- Classification Exercises A,B
  - Simple Gaussians
- Classification Exercise C
  - Real HEP example H→ZZ→41
- Regression Exercise D
  - Toy calorimeter regression

Optional exercises: Advanced classification BNN regression

### Summary

- Machine learning provides powerful multivariate methods for many classification/regression problems in HEP
- Ensemble methods are powerful extensions of these methods
- Comprehensive tools developed by HEP community widely used (TMVA, SPR, Paradigm)
  - − try them <sup>©</sup>

Plenty of problems await to be TACKLED!

# Proceed to Classification Tutorial B

### **Additional Material**

### Hilbert's 13th Problem

#### **Problem 13: Prove the conjecture**

In general, it is *impossible* to do the following:

$$f(x_1,...,x_n) = F(g_1(x_1),...,g_n(x_n))$$

But, in 1957, Kolmogorov *disproved* Hilbert's conjecture! Today, we know that functions of the form

$$f(x_1, \dots, x_I) = a + \sum_{j=1}^{H} b_j \tanh \left[ c_j + \sum_{i=1}^{I} d_{ji} x_i \right]$$

can provide arbitrarily accurate approximations. (Hornik, Stinchcombe, and White,

Neural Networks 2, 359-366 (1989))

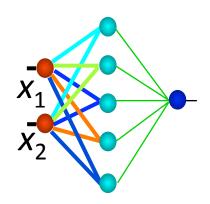

# Bayesian Neural Networks (BNN)

# **Bayesian Neural Networks**

Given: 
$$p(w \mid T) = p(T \mid w) p(w) / p(T)$$

over the parameter space of the functions

$$n(x, w) = 1 / [1 + exp(-f(x, w))]$$

can estimate  $p(s \mid x)$  as follows

$$p(s \mid x) \sim n(x) = \int n(x, w) p(w \mid T) dw$$

n(x) is called a **Bayesian Neural Network** (BNN)

# **Bayesian Neural Networks**

#### **Generate Sample**

N points  $\{w\}$  from  $p(w \mid T)$  using a Markov chain Monte Carlo (MCMC) technique and

average over the last *M* points

$$n(x) = \int n(x, w) p(w \mid T) dw$$

$$\sim \sum n(x, w_i) / M$$

### H to ZZ to 4Leptons

#### **Dots**

$$p(s \mid x) = H_s / (H_s + H_b)$$
  
 $H_s$ ,  $H_b$ , 1-D histograms

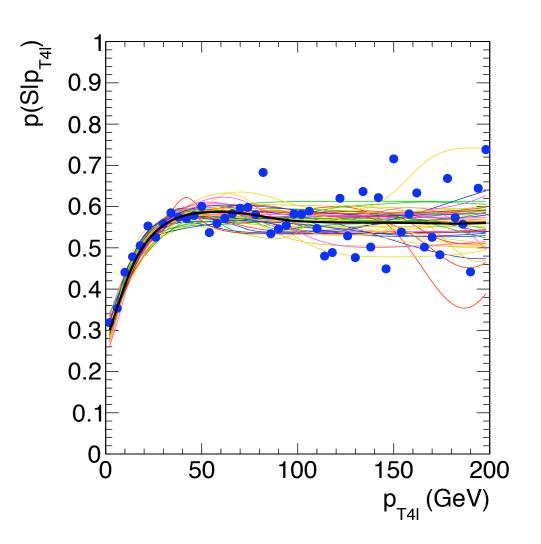

#### **Curves**

Individual NNs

$$n(x, w_k)$$

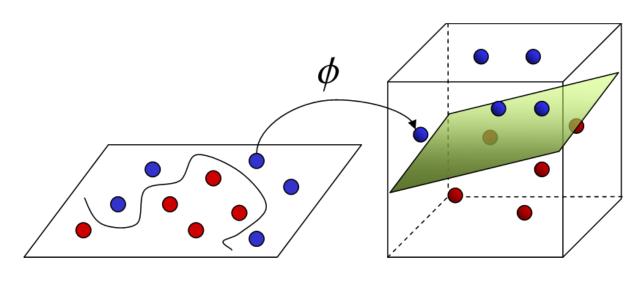

#### Black curve

$$n(x) = < n(x, w) >$$

**Input Space** 

Feature Space

#### Generalization of the Fisher discriminant

Boser, Guyon and Vapnik, 1992

#### **Basic Idea**

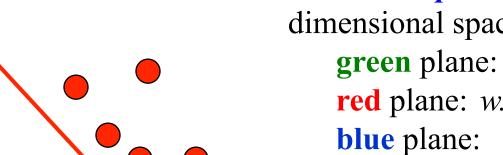

Data that are non-separable in *d*-dimensions may be better separated if mapped into a space of higher (usually, infinite) dimension

$$h:\mathfrak{R}^d\to\mathfrak{R}^\infty$$

As in the Fisher discriminant, a hyper-plane is used to partition the high dimensional space  $f(x) = w \cdot h(x) + c$ 

 $h(x_1)$ 

Consider *separable* data in the high dimensional space

**green** plane: w.h(x) + c = 0

**red** plane:  $w.h(x_1) + c = +1$ 

**blue** plane:  $w.h(x_2)+c=-1$ 

subtract blue from red

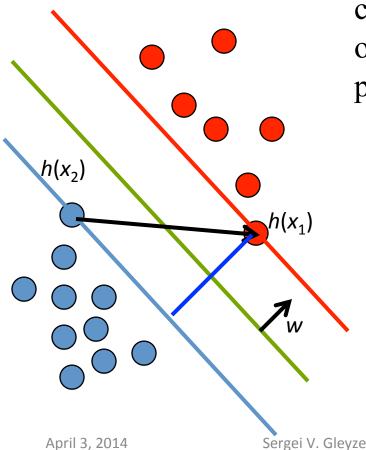

$$w.[h(x_1) - h(x_2)] = 2$$

and normalize the high dimensional vector w  $\hat{\mathbf{w}}.[h(\mathbf{x}_1) - h(\mathbf{x}_2)] = 2/||w||$ 

 $h(x_2)$ 

 $m = \hat{\mathbf{w}} \cdot [h(x_1) - h(x_2)]$ , the distance between the red and blue planes, is called the **margin**. The best separation occurs when the margin is as large as possible.

Note: because  $m \sim 1/||w||$ , maximizing the margin is equivalent to minimizing  $||w||^2$ 

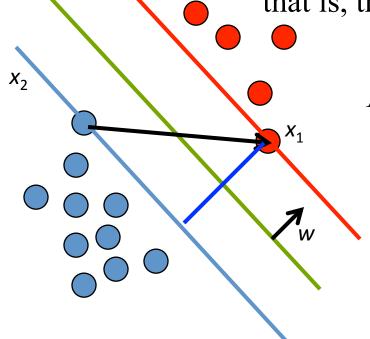

Label the **red** dots y = +1 and the **blue** dots y = -1. The task is to minimize  $||w||^2$  subject to the constraint

$$y_i (w.h(x_i) + c) \ge 1, \quad i = 1 ... N$$

that is, the task is to minimize

$$L(w,c,\alpha) = \frac{1}{2} \|w\|^2$$
$$-\sum_{i=1}^{N} \alpha_i \left[ y_i \left( w \cdot h(x_i) + c \right) - 1 \right]$$

where the  $\alpha > 0$  are Lagrange multipliers

When  $L(\mathbf{w}, \mathbf{c}, \boldsymbol{\alpha})$  is minimized with respect to w and c, the function  $L(\mathbf{w}, \mathbf{c}, \boldsymbol{\alpha})$  can be transformed to

$$E(\alpha) = \sum_{i=1}^{N} \alpha_i - \frac{1}{2} \sum_{i=1}^{N} \sum_{j=1}^{N} \alpha_i \alpha_j y_i y_j h(x_i) \cdot h(x_j)$$

At the minimum of  $E(\alpha)$ , the only non-zero coefficients  $\alpha$  are those corresponding to points *on* the **red** and **blue** planes: the so-called **support vectors**. The key idea is to replace the scalar product  $h(x_i).h(x_j)$  between two vectors of infinitely many dimensions by a **kernel function**  $K(x_i, x_j)$ .

• The (unsolved) problem is how to choose the correct kernel for a given problem?

# **Genetic Algorithms**

Central idea: adaptation. Inspired by evolutionary biology concepts of mutation, selection, cross-over (recombination) J.H. Holand, 1975

Begin with a large population of random solutions

- Evaluate each one
  - Fitness function (some form of  $S/\sqrt{B}$ )
  - Keep the best subset
    - Use it to build new solutions
    - Allow mutation, cross-over
    - Optimize over number of epochs/cycles

Used most frequently in HEP for rectangular cut optimization (computationally intensive)

#### **Extensions**

#### **Classification**

• Relatively easy to extend existing classifiers to handle more classes: just add more classes

#### Regression

- Very hard to do well
  - Nevertheless, very practical
- Less explored area in machine learning

# For problems that require simultaneous estimation of N functions (that are possibly related)

- N single-function regression model solution is too cumbersome
- Also less accurate
- Correlations among functions may be important and need to be accounted for

# Multi-function regression models are a better solution in this case

# Multi-Objective Model

- Properly take into account dependencies between output attributes (their correlations)
- improved performance results compared to single-objective models, especially in ensembles
  - usually smaller and easier to interpret
  - very useful for transformations

### **Predictive Clustering**

# Example of a multi-function regression model based on trees or rules

- Decision trees are equated to clustering trees
   by P. Langley in 1996, first noted by Fisher in
   1993
- Cluster "hierarchy"
  - Each tree node corresponds to a cluster Root node contains full dataset partitioned recursively into sub-clusters

# **Clustering Concept**

# Use decision tree induction to obtain clusters with:

- minimal intra-cluster distance
  - between examples from the same cluster
- maximal inter-cluster distance
  - between examples from different clusters
  - In classification trees distance metric is class enthropy

# Clustering Example

- 14 input variables {a, b, c, d...}
  - 4 of them strongly correlated
- 14 target outputs to estimate {A, B, C, D...}
  - 4 of them strongly correlated

**Challenge:** build a predictive model to describe simultaneously all the outputs {A,B,C,D...}, provided a corresponding set of inputs.

For example: These can be correlated EM shower-shapes

#### **CLUS 2.0**

#### Predictive clustering implementation

- Decision tree and rule induction system
- Designed for multi-task learning and multi-label classification
- Well-suited for both classification and regression problems

### **Learning Procedure**

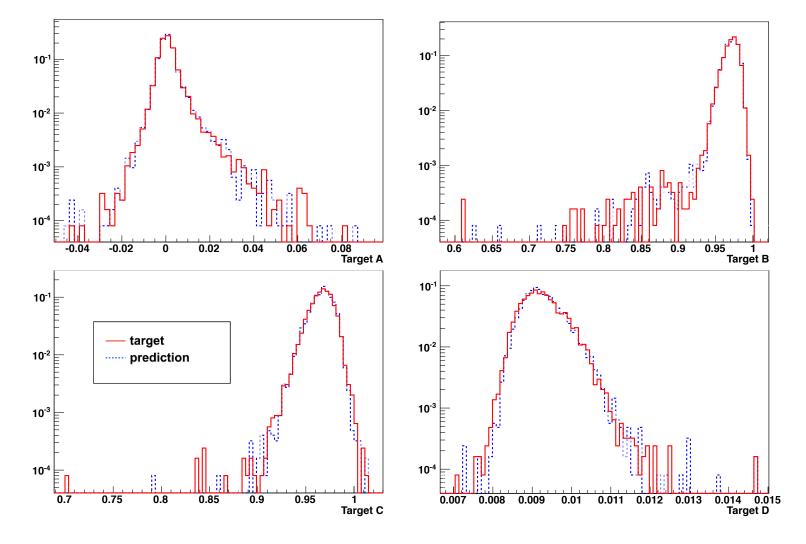

**Train** the predictive clustering model by providing a "map" between inputs and outputs. Let it learn.

Evaluate: Use the Test set to compare predictions on "unseen" data to the Target values of the outputs.

# Illustrative Example

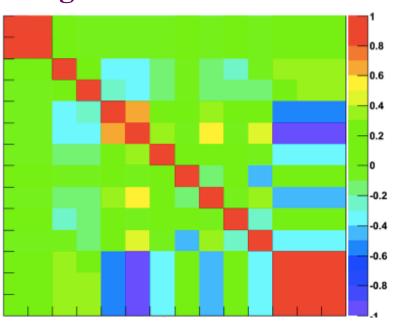

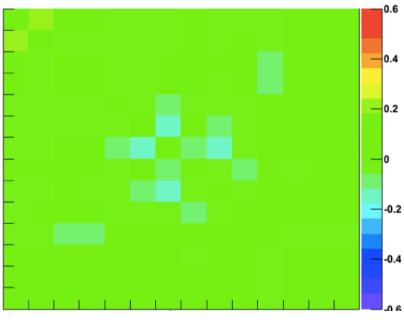

#### **Correlations**

#### **Target Correlations**

#### **Prediction-Target Difference**

Very close to Zero

### **Clustering Rules**

Clustering rules can be constructed from predictive clustering trees

Main difference: simple rules focus on the accuracy connected to the target

#### Predictive clustering rules focus on:

- target attribute accuracy
- tight or compact rule coverage of the instances by computing their distance metric

# **Summary II**

- Many multivariate methods available: pick the one that best suits your problem
  - Good starting points: random grid search, boosted decision trees, neural networks
  - Then: support vector machines, random forests, bayesian neural networks, predictive clustering
- Both classification and regression can be generalized to multiple classes and targets
  - Predictive clustering is a good example of both
